1. Module Overview

The RapID Platform Network Interface with REM Switch module contains everything needed including the communications controller, protocol stacks, Flash, RAM, and PHYs. Figure 1 provides an overview of the module.

Figure 1 – Overview of Module Components and Interfaces

The remainder of this document provides technical details for the Network Interface with REM Switch module and the information necessary to integrate the module into a circuit card.

2. Physical Dimensions and Connector Pinout

This paragraph describes the process for installing the Network Interface with REM Switch module in a field device's application hardware. The process is straightforward and consists of designing a low-cost socket into the application hardware to provide signal interface and power connections. Only a single +3.3V power supply is required. In addition, a UART or parallel interface is used to communicate with a host processor.

Any unused module inputs may be left floating. The appropriate pull-up resistors are included on the module.

2.1 Physical Constraints

The Network Interface with REM Switch module is 2.382" (60,5mm) x 2.216" (56,3mm) as shown in Figure 2. The module height from the X1 seating plane is 0.715" (18,2mm) as shown in Figure 3. The RJ45 (Ethernet) connector and all LEDs are conveniently located along one edge of the PC board for easy access. The RJ45 connector extends 3.0mm past the edge of the PC board to allow for installation in an enclosure. The LEDs are flush with the PC board edge. The Link/Activity LEDs for Ethernet ports 1 and 2 are located inside the RJ45 connector. The power and bi-color LED indicators are on the top side of the PC board as shown in Figure 3.

All components on the bottom of the PC board are above the X1 connector seating plane, as shown in Figure 3. All components on the application hardware that are within the Network Interface with REM Switch module outline should be shorter than the target system's X1 mating connector to prevent physical interference. The recommended mating connector defined in the next paragraph (SSW-116-21-F-D) has a height of 0.335" (8,51mm). If the recommended mating connector is used, all components within the Network Interface with REM Switch module outline should be shorter than 0.335" (8,51mm).

Figure 2 - Dimensions of the Network Interface with REM Switch Module (Plane View)

Figure 3 - Dimensions of the Network Interface with REM Switch Module (Cross-section)

2.2 Signal Interface Connector

The module is installed into the target system using a 64 pin, 0.1" (2,54mm) pitch socket. This socket consists of 4 rows of 16 pins, as shown in Figure 4. The connector reference designator in the Network Interface with REM Switch module schematic is X1. The 4 rows are designated A, B, C and D. Rows A and B are on 0.1" (2,54mm) centers, as are rows C and D. The connector can be implemented by using 2 dual row connectors, 1 for rows A and B, and 1 for rows C and D. The recommended connector for each of these is Samtec part number SSW-116-21-F-D.

The additional plated through hole shown in Figure 4 is a mounting hole. It is connected to chassis ground on the Network Interface with REM Switch module. This plated through hole is a 0.125" (3,175mm) hole with a 0.250" (6,35mm) pad.

2.3 Connector Pinout

A summary on the pinout is shown in Figure 6 and the detailed pin definition is provided in the following tables. All signals use 3.3V logic levels. All inputs **except** **MAN_RESET_N** are 5 volt tolerant. **MAN_RESET_N** is **not** 5 volt tolerant, and must be supplied a +3.3V signal.

Chassis ground is provided on pin X1-C10 for additional shielding of the Ethernet network components.

Figure 6 - Summary of Connector Pin Names

| D15 | UIC1_15 | Output | Read Data Bit 15 for Parallel Host Interface |
| D16 | NC | Not Connected | Spare pin |

2.4 Power requirements

The Network Interface with REM Switch module consumes approximately 1.8W, supplied from a single +3.3V supply. The power supply requirements for voltage and current are $+3.3V \pm 10\%$, 800mA. The 3.3V power is supplied to pins X1-B1 and X1-B9 and ground is connected to pins X1-C1 and X1-C9.

2.5 Reset Requirements

The Network Interface with REM Switch module may be reset by the application hardware. Module signal X1-B8, referred to as MAN_RESET_N is the reset input to the Network Interface with REM Switch module. This input is connected to the manual reset input of the on-board reset supervisor (U2). U2 is a TC1270A voltage supervisor chip which requires a low pulse for a minimum of 10uS in order to generate a valid reset.

Since the module does have an on-board supervisor IC, it may be allowed to initialize without an external reset source. Module signal X1-B16, referred to as RESET_OUT_N, is an output that indicates if the module is in a reset state. The signal will go low to indicate the reset state is active.

Regardless of how the module is reset, it will not be available for communication until the software has initialized the module and entered the operating state. The time required for the module to enter the operating state is 1.0 second after the receipt of a valid reset pulse or after power is valid if no external reset source is used.

3. Communication Interfaces between the Host Processor and Network Interface with REM Switch Module

The Network Interface with REM Switch module requires a host processor, and may interface to the host via a UART (serial) or a 16-bit parallel interface. Implementation of each of these interfaces is described in the following paragraphs.

3.1 UART Host Interface

The UART Host Interface is implemented using two pins from the Network Interface with REM Switch module. These pins are X1-C3 and X1-C4. The signal names for these pins, as shown in

Table 3, are UIC1_16 and UIC1_0, respectively. UIC1_16 is the Network Interface with REM Switch module's TX signal, and UIC1_0 is the Network Interface with REM Switch module's RX signal. The Network Interface with REM Switch module's TX signal must be connected to the Host Processor's RX signal, and the Network Interface with REM Switch module's RX signal must be connected to the Host Processor's TX signal. Figure 7 provides an overview of these signal connections.

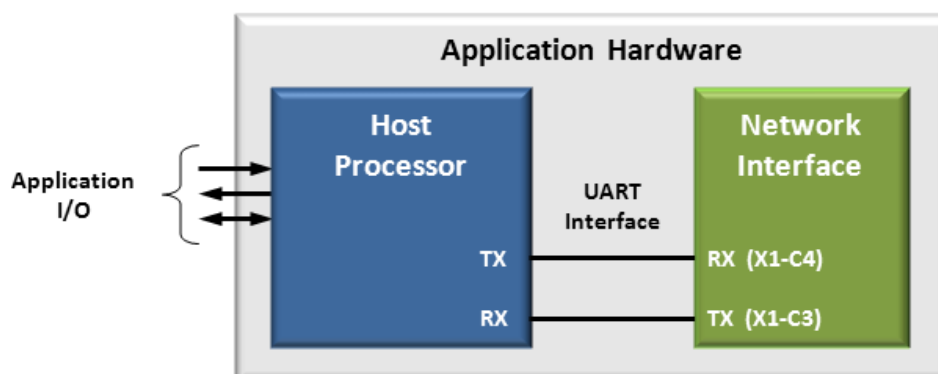

Figure 7 – UART Host Interface Connection

3.2 Parallel Host Interface

The Parallel Host Interface is implemented as a 16-bit read FIFO and a 16-bit write FIFO. Support circuitry between the Host Processor and Network Interface with REM Switch is required and must be designed into the application hardware. The host processor connects to a 16-bit data bus and uses 4 control signals to either read or write data to/from the Network Interface with REM Switch module. Figure 8 provides an overview of these connections.

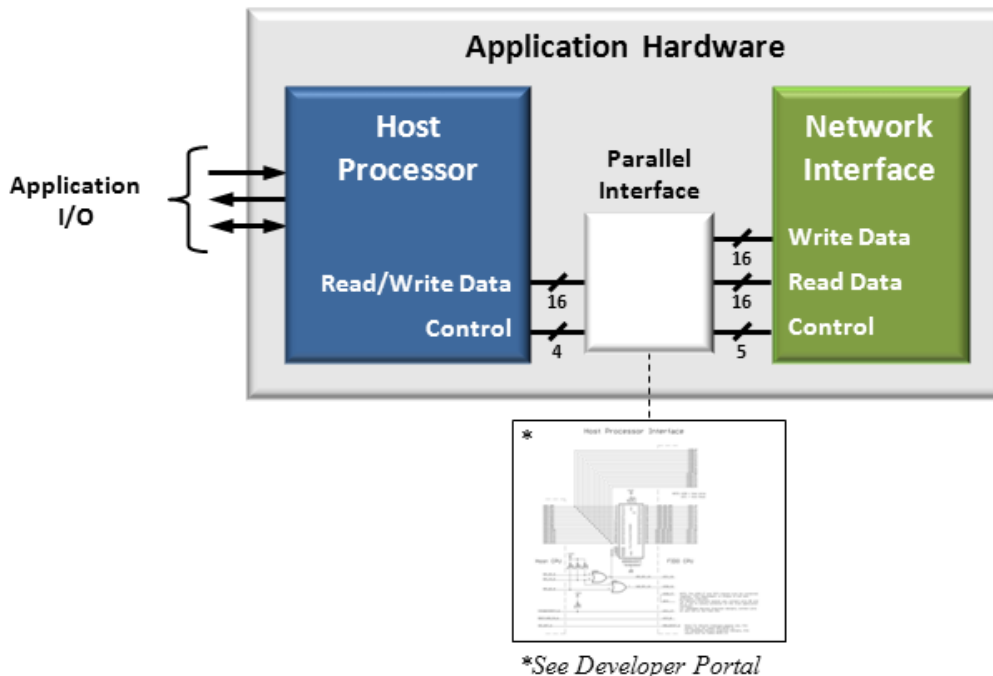

Figure 8 – Parallel Host Interface Connection

Refer to the “HPI Personality Module” schematic (SCH-NI_100-EDB-001) for details on the circuitry required for the Parallel Host Interface. The pinout tables above may be used to understand the signal names in the schematic. The 16-bit data bus on the host side of the interface is referred to as HPI_D0 through HPI_D15. The four control signals are referred to as HPI_OE_N, HPI_CS_N, HPI_WE_N, and FIFONOTEMPTY_N. As noted in the schematics, it is important that signal pins X1-A9 and X1-A8 on the Network Interface with REM Switch module’s connector be tied together when integrating the module on the application hardware.

Refer to the “Host Processor Interface User Guide.pdf” for a detailed description of the Parallel Host Interface. These documents are found on the Network Interface with REM Switch Tools page in the Developer Portal on the Innovasic website.

4. Considerations for Production and Maintenance

There are three methods for configuring and programming the Network Interface with REM Switch module during production of end use systems. These methods are:

1. Bootloader
2. JTAG
3. Flash Programmer

The Bootloader and JTAG methods can also be used to perform field updates during maintenance for the end devices. The subparagraphs below provide an overview of these methods. Figure 9 shows the connections and devices involved for all three methods for either a module or embedded design.

Figure 9 – Programming Connections and Devices

4.1 Boot Loader

Innovasic supports programming flash chips on the Network Interface with REM Switch module or embedded design using the Ethernet connector. The type of programming file used to support this is called a .load file. Innovasic supplies .load files for each software component in the Network Interface with REM Switch module. These components are identified as:

- Boot Loader
- Unified Interface
- Network
- Configuration Data

These .load file types are available on the Network Interface with REM Switch module Software page in the Developer Portal on the Innovasic website, and can be loaded as described in the “Boot Loader User Guide.pdf”.

It is important to note that the BOOTLOADER_EN_N signal **must be** grounded when the Network Interface with REM Switch module powers-up in order to enter the programming mode. This is an important consideration if the final product requires field updates.

4.2 JTAG

Innovasic supports programming flash chips on the Network Interface with REM Switch module or embedded design using the JTAG Connector. The type of programming file used to support this is called a .elf file. Innovasic supplies .elf files for each software component in the Network Interface with REM Switch module. These components are identified as:

- Boot Loader
- Unified Interface
- Network
- Configuration Data

These .elf file types are available on the Network Interface with REM Switch Software page in the Developer Portal on the Innovasic website.

Using the JTAG method for configuring and programing the Network Interface with REM Switch module requires a PC, JTAG “wiggler” and programming software, and .elf programming files. The wiggler and programming software may be ordered from Innovasic using part number “RapID-PGMR VMCGR”.

A connector compatible with the ribbon-cable side of the wiggler is already installed on the module as shown in Figure 9. This connector must be used in the embedded design. The ribbon cable on the wiggler connects to the module/embedded design connector. The other end of the

wiggler connects to the USB port of the PC. Detailed instructions for loading and programming with the .elf files are provided with the JTAG programming software.

Note that it is possible to program blank flash using the JTAG method. This method is useful if a Flash Programmer is not available. Access to the JTAG connector is required; however, grounding BOOTLOADER_EN_N is not required.

4.3 Flash Programmer

Innovasic supports programming individual, blank flash chips using a flash programmer. The type of programming file used to support this is called a Motorola S record file (.srec). Innovasic supplies .srec files for each software component in the Network Interface with REM Switch module. These components are identified as:

- Boot Loader
- Unified Interface
- Network
- Configuration Data

These .srec file types are available in the Developer Portal on the Innovasic website, and can be sequentially loaded into the flash programmer. There is no need to be concerned the data will overlap. Once the files are loaded into the programmer the complete executable package can be programmed into the flash chip.

5. Revision History

Table 5 – Document Revision History

| Date | Revision | Description | Page(s) |
|----------------|----------|-----------------|---------|
| April 10, 2014 | 00 | Initial release | NA |

6. For Additional Information

The Innovasic Support Team is continually planning and creating tools for your use. Visit <http://www.innovasic.com> for up-to-date documentation and software. Our goal is to provide timely, complete, accurate, useful, and easy-to-understand information. Please feel free to contact our experts at Innovasic at any time with suggestions, comments, or questions.
