TDA7405

EQUALIZER CARRADIO SIGNAL PROCESSOR

1 FEATURES

- 3 STEREO INPUTS
- 3 MONO INPUTS
- DYNAMIC-COMPRESSION-STAGE FOR CD
- BASS, TREBLE AND LOUDNESS CONTROL
- EQ-FILTERS FOR SEPARATE FRONT/REAR-EQUALIZATION
- VOICE-BAND-FILTER FOR MIXING-CHANNEL
- DIRECT MUTE AND SOFTMUTE
- INTERNAL BEEP
- FOUR INDEPENDENT SPEAKER-OUTPUTS
- INDEPENDENT SECOND SOURCE-SELECTOR
- FULL MIXING CAPABILITY
- PAUSE DETECTOR

1.1 Stereodecoder

- RDS MUTE
- NO EXTERNAL ADJUSTMENTS
- AM/FM NOISEBLANKER WITH SEVERAL TRIGGER CONTROLS
- PROGRAMMABLE MULTIPATH DETECTOR
- QUALITY DETECTOR OUTPUT

Part Number	Package
TDA7405	TQFP44

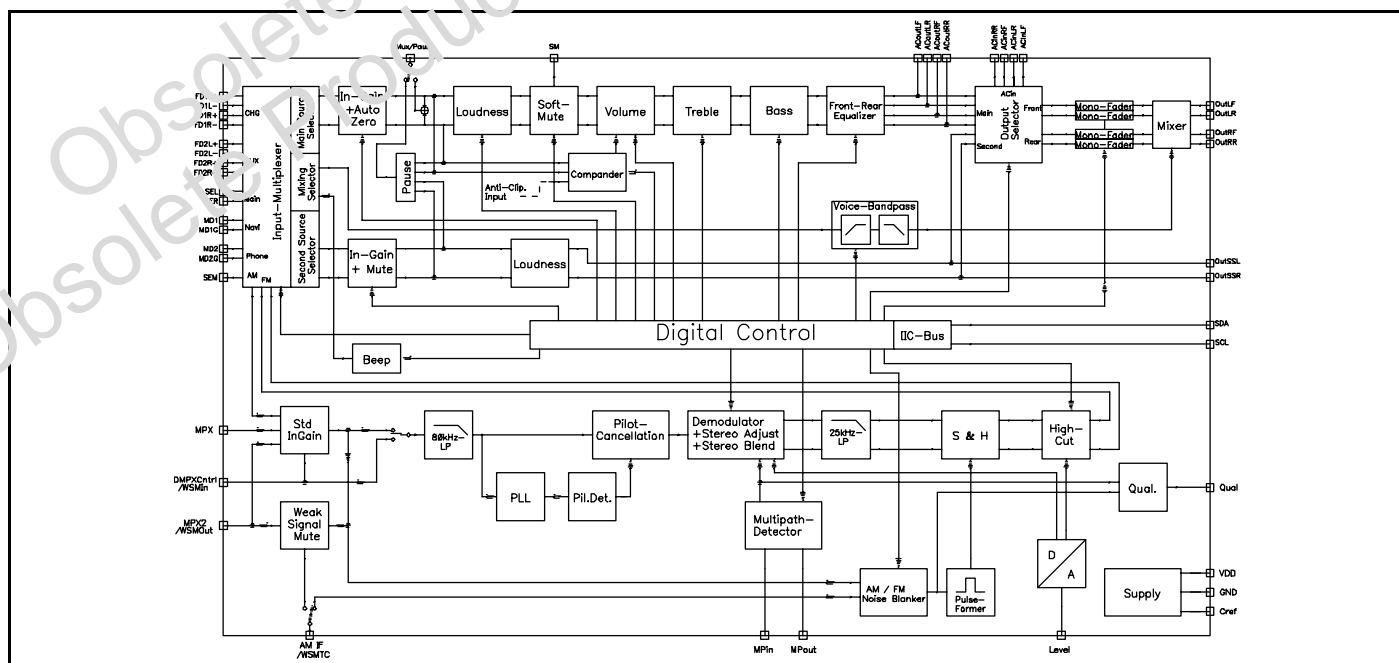

1.2 Digital control

- I²C-BUS INTERFACE

2 DESCRIPTION

The device includes a high performance audioprocessor and a stereodecoder-noiseblanker combination with the whole low frequency signal processing necessary for state-of-the-art as well as future carradios. The digital control allows a programming in a wide range of all the filter characteristics. Also the stereodecoder part offers several possibilities of programming especially for the adaptation to different IF-devices.

4 AUDIOPROCESSOR PART

Features:

Input Multiplexer	2 fully differential CD stereo inputs with programmable attenuation 1 single-ended stereo input 2 differential mono input 1 single-ended mono input In-Gain 0..15dB, 1dB steps internal Offset-cancellation (AutoZero) separate second source-selector
Beep	internal Beep with 3 frequencies + diagnostic setting (19kHz tone)
Mixing stage	Beep, Phone, Navigation and FM mixable to all speaker-outputs (see Figure 20) programmable Voice-Band Filter
Loudness	programmable center frequency and frequency response 15 x 1dB steps selectable flat-mode (constant attenuation)
Volume	0.5dB attenuator 100dB range soft-step control with programmable times
Bass	2nd order frequency response center frequency programmable in 8 steps DC gain programmable ± 15 x 0.5dB steps
Treble	2nd order frequency response center frequency programmable in 4 steps ± 15 x 1dB steps
Equalizer	two stereo equalizing-filters for separate front/rear adaption 1st filter center-frequency programmable in 16 steps (4 steps/octave, min 63Hz, max 840Hz) 2nd filter center-frequency programmable in 16 steps (4 steps/octave, min 300Hz, max 4kHz) quality factor programmable in 4 steps ± 15 x 1dB steps selectable flat-mode
Speaker	4 independent speaker controls in 1dB steps control range 95dB separate Mute
Mute Functions	direct mute digitally controlled SoftMute with 4 programmable mute-times
Pause Detector	programmable threshold
Compander	dynamic range compression for use with CD 2:1 compression rate programmable max. gain

TDA7405

5 DESCRIPTION OF THE AUDIOPROCESSOR PART

5.1 Input stages

In the basic configuration two full-differential, two mono-differential, one single ended stereo and one single-ended mono input are available. In addition a dedicated input for the stereodecoder MPX-signal is present.

Figure 5. Input stages

5.1.1 Full-differential stereo Input 1 (FD1)

The FD1-input is implemented as a buffered full-differential stereo stage with 100kΩ input-impedance at each input. The attenuation is programmable in 3 steps from 0 to -12dB in order to adapt the incoming signal level. A 6dB attenuation is included in the differential stage, the additional 6dB are done by a following resistive divider. This input is also configurable as two single-ended stereo inputs (see pin-out).

5.1.2 Full-differential stereo Input 2 (FD2)

The FD2-input has the same general structure as FD1, but with a programmable attenuation of 0 or 6dB embedded in the differential stage.

5.1.3 Mono-differential Input 1 (MD1)

The MD1-input is designed as a basic differential stage with 56k Ω input-impedance. This input is configurable as a single-ended stereo input (see pin-out).

5.1.4 Mono-differential Input 2 (MD2)

The MD2-input has the same topology as MD1, but without the possibility to configure it to single ended.

5.1.5 Single-ended stereo Input (SE1), single-ended mono input (AM) and FM-MPX input

All single ended inputs offer an input impedance of 100k Ω . The AM-pin can be connected by software to the input of the stereodecoder in order to use the AM-Noiseblanker and AM-High-Cut feature.

5.2 AutoZero

The AutoZero allows a reduction of the number of pins as well as external components by canceling any offset generated by or before the In-Gain-stage (Please notice that externally generated offsets, e.g. generated through the leakage current of the coupling capacitors, are not canceled).

The auto-zeroing is started every time the DATA-BYTE 0 is selected and needs max. 0.3ms for the alignment. To avoid audible clicks the Audioprocessor is muted before the loudness stage during this time. The AutoZero-feature is only present in the main signal-path.

5.2.1 AutoZero for Stereodecoder-Selection

A special procedure is recommended for selecting the stereodecoder at the main input-selector to guarantee an optimum offset-cancellation:

(Step 0: SoftMute or Mute the signal-path)

Step 1: Temporary deselect the stereodecoder at all input-selectors

Step 2: Configure the stereodecoder via IIC-Bus

Step 3: Wait 1ms

Step 4: Select the stereodecoder at the main input-selector first

The root cause of this procedure is, that after muting the stereodecoder (Step 1), the internal stereodecoder filters have to settle in order to perform a proper offset-cancellation.

5.2.2 AutoZero-Remain

In some cases, for example if the μ P is executing a refresh cycle of the IIC-Bus-programming, it is not useful to start a new AutoZero-action because no new source is selected and an undesired mute would appear at the outputs. For such applications the A631 could be switched in the AutoZero-Remain-Mode (Bit 6 of the subaddress-byte). If this bit is set to high, the DATA-BYTE 0 could be loaded without invoking the AutoZero and the old adjustment value remains.

5.3 Pause Detector / MUX-Output

The pin number 40(Pause/MUX) is configurable for two different functions:

1. During Pause-Detector OFF this pin is used as a mono-output of the main input-selector. This signal is often used to drive a level-/equalizer-display on the carradio front-panel.
2. During Pause-Detector ON the pin is used to define the time-constant of the detector by an external capacitor.

The pause-detector is driven by the internal stereodecoder-outputs in order to use pauses in the FM-signal for alternate-frequency-jumps. If the signal-level of both stereodecoder channels is outside the programmed voltage-window, the external capacitor is abruptly discharged. Inside the pause-condition the capacitor is slowly recharged by a constant current of 25 μ A. The pause information is also available via IIC-Bus (see IIC-Bus programming).

TDA7405

5.4 Loudness

There are four parameters programmable in the loudness stage:

5.4.1 Attenuation

Figure 6 shows the attenuation as a function of frequency at $f_P = 400\text{Hz}$.

Figure 6. Loudness Attenuation @ $f_P = 400\text{Hz}$

5.4.2 Peak Frequency

Figure 7 shows the four possible peak-frequencies at 200, 400, 600 and 800Hz

Figure 7. Loudness Center frequencies @ Attn. = 15dB

5.4.3 Loudness Order

Different shapes of 1st and 2nd-Order Loudness

Figure 8. 1st and 2nd Order Loudness @ Attn. = 15dB, fP=400Hz

5.4.4 Flat Mode

In flat mode the loudness stage works as a 0dB to -19dB attenuator.

5.5 SoftMute

The digitally controlled SoftMute stage allows muting/demuting the signal with a I2C-bus programmable slope. The mute process can either be activated by the SoftMute pin or by the I2C-bus. This slope is realized in a special S-shaped curve to mute slow in the critical regions (see Figure 9). For timing purposes the Bit of the I2C-bus output register is set to 1 from the start of muting until the end of de-muting.

Figure 9. Softmute-Timing

Note: Please notice that a started Mute-action is always terminated and could not be interrupted by a change of the mute -signal.

TDA7405

5.6 SoftStep-Volume

When the volume-level is changed audible clicks could appear at the output. The root cause of those clicks could either be a DC-Offset before the volume-stage or the sudden change of the envelope of the audiosignal. With the SoftStep-feature both kinds of clicks could be reduced to a minimum and are no more audible. The blend-time from one step to the next is programmable in four steps.

Figure 10. SoftStep-Timing

Note: For steps more than 0.5dB the SoftStep mode should be deactivated because it could generate a hard 1dB step during the blend-time

5.7 Bass

There are four parameters programmable in the bass stage:

5.7.1 Attenuation

Figure 11 shows the attenuation as a function of frequency at a center frequency of 80Hz.

Figure 11. Bass Control @ $f_C = 80\text{ Hz}$, $Q = 1$

5.7.2 Center Frequency

Figure 12 shows the eight possible center frequencies 60, 70, 80, 90, 100, 130, 150 and 200Hz.

Figure 12. Bass center Frequencies @ Gain = 14dB, Q = 1

5.7.3 Quality Factors

Figure 13 shows the four possible quality factors 1, 1.25, 1.5 and 2.

Figure 13. Bass Quality factors @ Gain = 14dB, fC = 80Hz

TDA7405

5.7.4 DC Mode

In this mode the DC-gain is increased by 4.4dB. In addition the programmed center frequency and quality factor is decreased by 25% which can be used to reach alternative center frequencies or quality factors.

Figure 14. Bass normal and DC Mode @ Gain = 14dB, $f_C = 80\text{Hz}$

Note: The center frequency, Q and DC-mode can be set fully independently.

5.8 Treble

There are two parameters programmable in the treble stage:

5.8.1 Attenuation

Figure 15 shows the attenuation as a function of frequency at a center frequency of 17.5kHz.

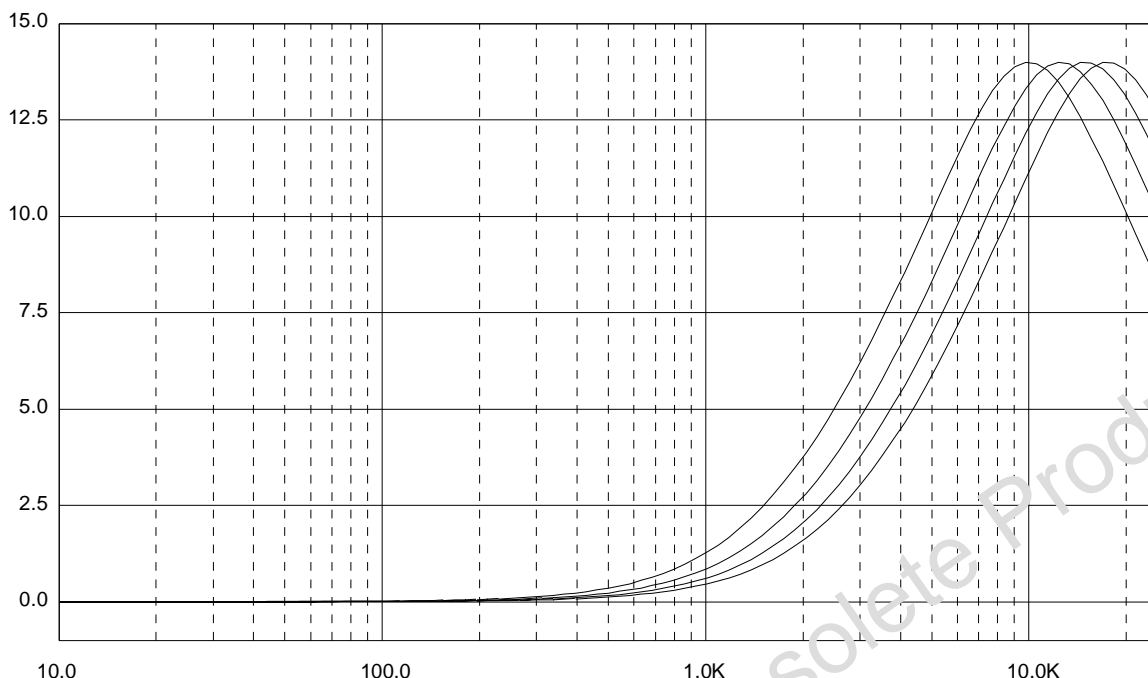

Figure 15. Treble Control @ $f_C = 17.5\text{kHz}$

5.8.2 Center Frequency

Figure 16 shows the four possible center frequencies 10k, 12.5k, 15k and 17.5kHz.

Figure 16. Treble Center Frequencies @ Gain = 14dB

5.9 EQ-Filter

There are two EQ-Filters present in the A631: one for the High-Frequency-Range and one for the Low-Frequency-Range with a certain overlap. They are programmable in center-frequency (4 frequencies/octave), in Q(4 settings) and in Attenuation (1dB-steps). In addition several configurations are possible to use the filters in the front- or rear-path.

Table 6. Gain, Center Frequency and Quality Factor of Equalizer Filters

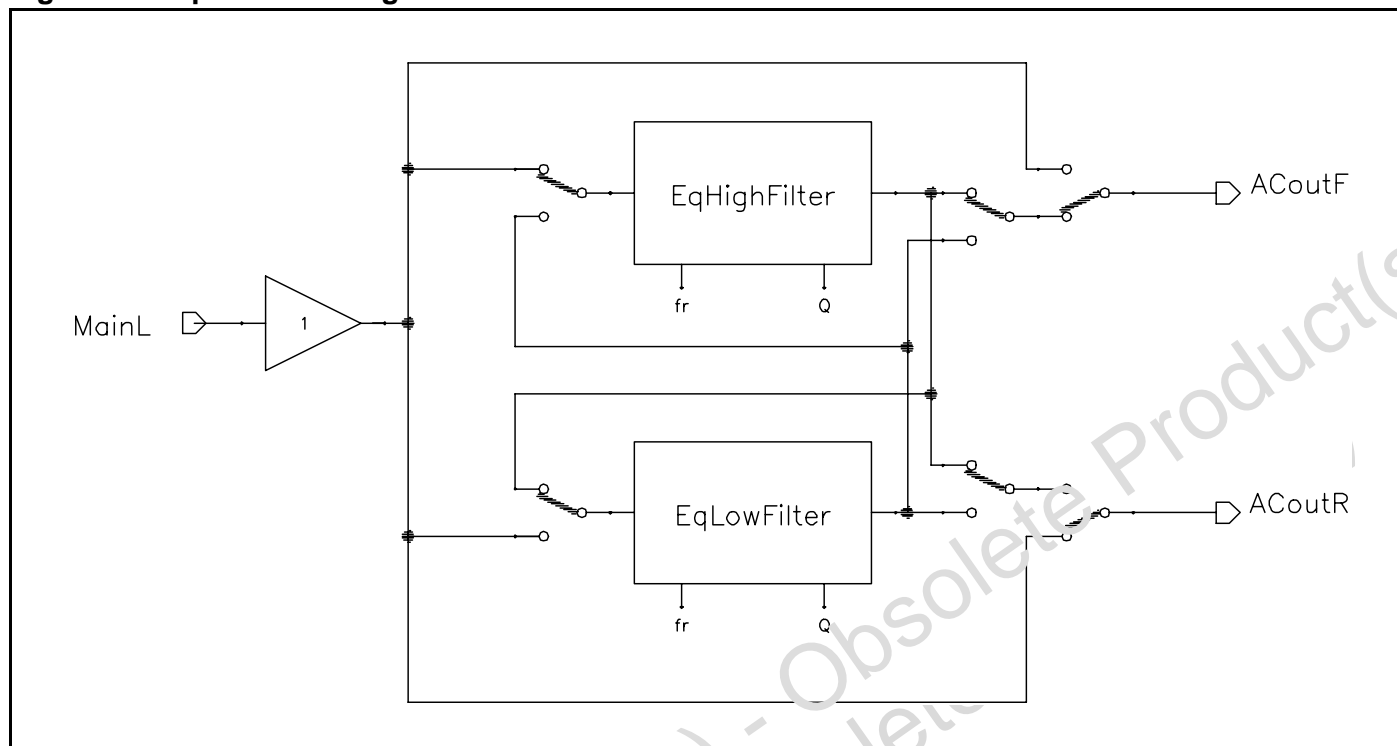

Parameter	Min	Max	Unit
Gain	-15	15	dB
Center Frequency Filter 1	63	840	Hz
Center Frequency Filter 2	300	4000	Hz
Quality Factor	1	4	

TDA7405

5.9.1 Equalizer-Setup

The two Filters can be configured in multiple ways in order to cover as most as possible applications. Both filters can be programmed to be either in the front- or in the rear-path, respectively. This feature enables to have e.g. the High-Filter in the front- and both filters in the rear-path.

Figure 17. Equalizer Configuration

5.9.2 Attenuation

Figure 18 shows the attenuation as a function of frequency at a center frequency of 625 Hz.

Figure 18. Gain/Attenuation of EQ-Filter

5.9.3 Frequencies

Figure 19. Center-Frequencies of EQ-Filter

5.9.4 Q-Factor

Figure 20 shows the four possible quality factors 1, 2, 3 and 4.

Figure 20. Different Q-factors of Equalizer-Filter

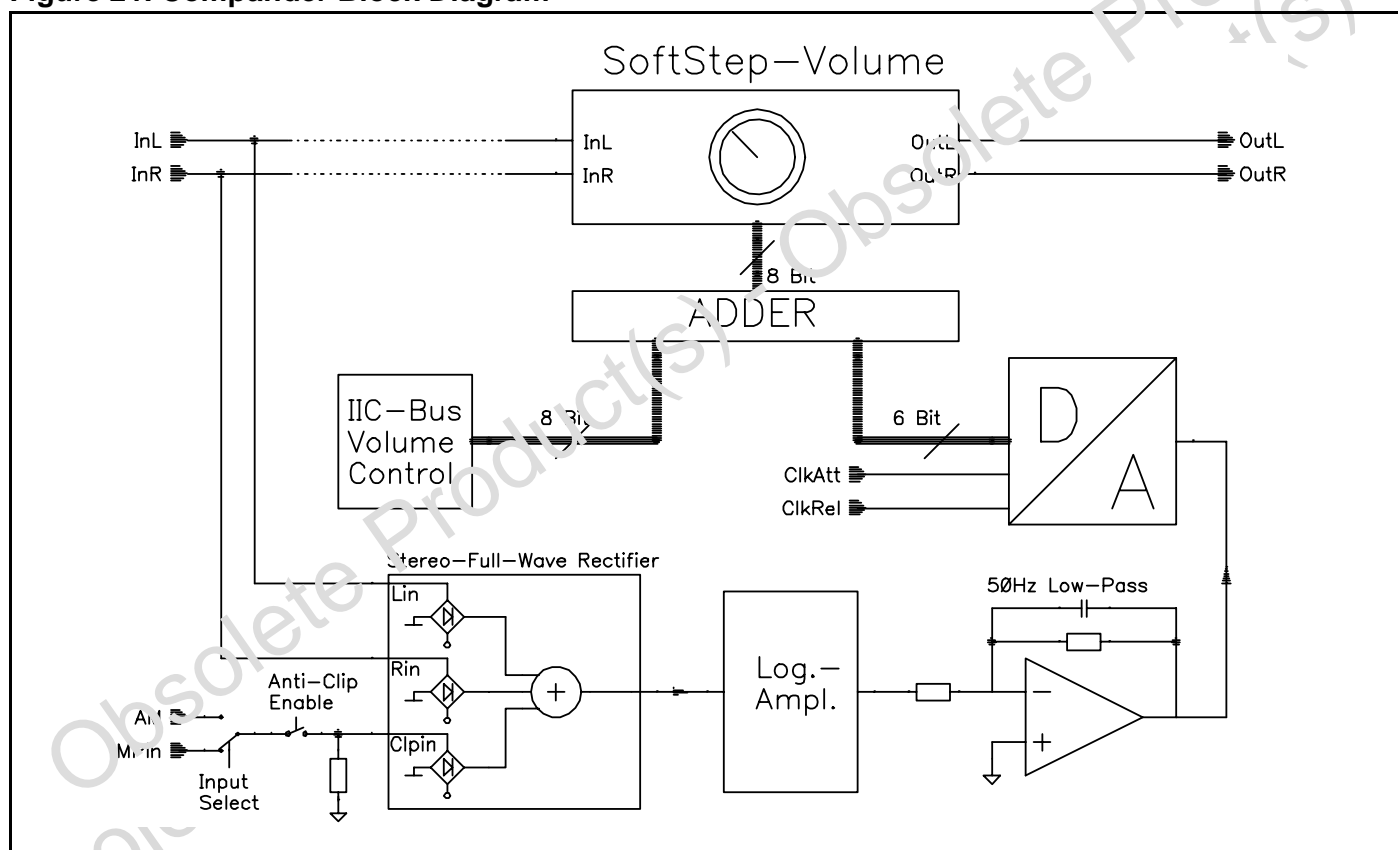

TDA7405

5.10 Comander

5.10.1 Signal-Compression

A fully integrated signal-compressor with programmable Attack- and Decay-times is present in the A631 (see Figure 20). The compander consists of a signal-level detection, an A/D-Converter plus adder and the normal SoftStep-Volume-stage. First of all the left and the right InGain-signal is rectified, respectively, and the logarithm is build from the summed signal. The following low-pass smooth the output-signal of the logarithm-amplifier and improves the low-frequency suppression. The low-pass output-voltage then is A/D-converted and added to the current volume-word defined by the IIC-Bus. Assuming reference-level or higher at the compander input, the output of the ADC is 0. At lower levels the voltage is increasing with 1 Bit/dB. It is obvious that with this configuration and a 0.5dB-step volume-stage the compression rate is fixed to 2:1 (1dB less at the input leads to 0.5dB less at the output). The internal reference-level of the compander is programmable in three steps from 0.5V_{RMS} to 2V_{RMS}. For a proper behavior of the compression-circuit it is mandatory to have at a 0dB input-signal exactly the programmed reference-level after the InGain-stage. E.g. at a configured reference-level of 0.5V_{RMS} the output of the InGain-stage has to have also 0.5V_{RMS} at 0dB source-signal (Usually the 0dB for CD is defined as the maximum possible signal-level). To adapt the external level to the internal reference-level the programmable attenuation in the differential-stages and the InGain can be used.

Figure 21. Comander Block Diagram

5.10.2 Anti-Clipping

In a second application the compander-circuit can be used for a Anti-Clipping or Limiting function. In this case one of the dedicated inputs (AM or MPin) is connected directly to the Clip-Detector of the Power-Amplifier. If no clipping is detected, the open-collector output of the Power-Amplifier is highohmic and the input-voltage of the rectifier is V_{REF}. The level-detector interprets this as a very small signal and reacts with the maximum programmed compander-gain. In the application this gain has to be compensated by decreasing the volume with the same value in order to get the desired output-level. In clipping situation the open-collector-current generates a voltage-drop at the rectifier-input, which forces the compander to decrease the gain until the clipping disappears.

It is even possible to run the compression-mode and the Anti-Clipping mode in parallel. In this case the maximum compander-Gain should be set to 29 dB.

5.10.3 Characteristic

To achieve the desired compression characteristic like shown below the volume has to be decreased by 4dB.

Figure 22. Componder Characteristic

5.10.4 I²C -BUS-Timing

When the Componder is active a volume- word coming from this stage is added to the I²C-Bus volume-word and the volume is changed with a soft slope between adjacent steps (SoftStep-stage). As mentioned in the description of this stage it is not recommended to change the volume during this slope. To avoid this behaviour while the Componder is working, and the volume has to be changed, the compander-hold-bit is implemented (Bit 7 in the subaddress-byte). The recommended timing for changing the volume during compander-ON is the following:

1. Set the compander-hold-bit
2. Wait the actual SoftStep-time
3. Change the volume
4. Reset the compander-hold-bit

The SoftStep-times are in compander-ON condition automatically adapted to the attack-time of the Componder. In the following table the related SoftStep-times are shown:

Attack-Time	SoftStep-Time
6ms	0.16ms
12ms	0.32ms
24ms	0.64ms

5.10.5 AC-Coupling

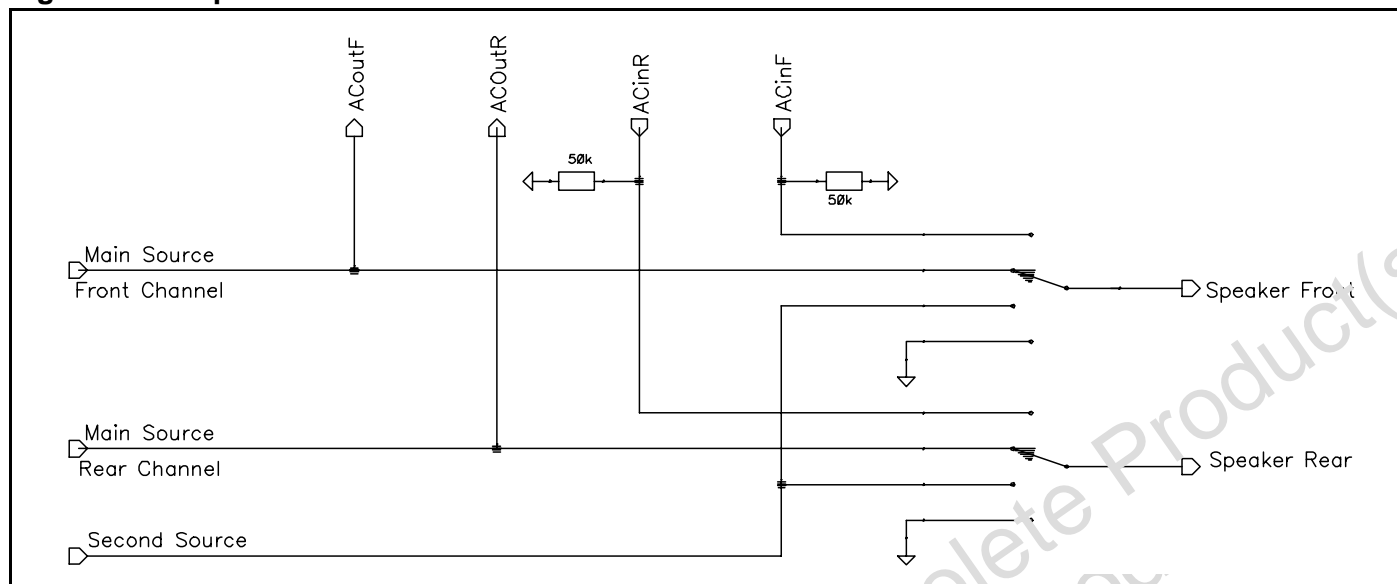

In some applications additional signal manipulations are desired, for example surround-sound or more-band-equalizing. For this purpose an AC-Coupling is placed before the speaker-attenuators, which can be activated or internally shorted by I²C-Bus. In short condition the input-signal of the speaker-attenuator is available at the AC-Outputs. The input-impedance of this AC-Inputs is 50kΩ.

TDA7405

5.10.6 Output Selector

The output-selector allows to connect the main- or the second-source to the Front-, Rear-speaker-attenuator, respectively. As an example of this programming the device is able to connect via software the main-source to the back (rear) and the second-source to the front (see Figure 23).

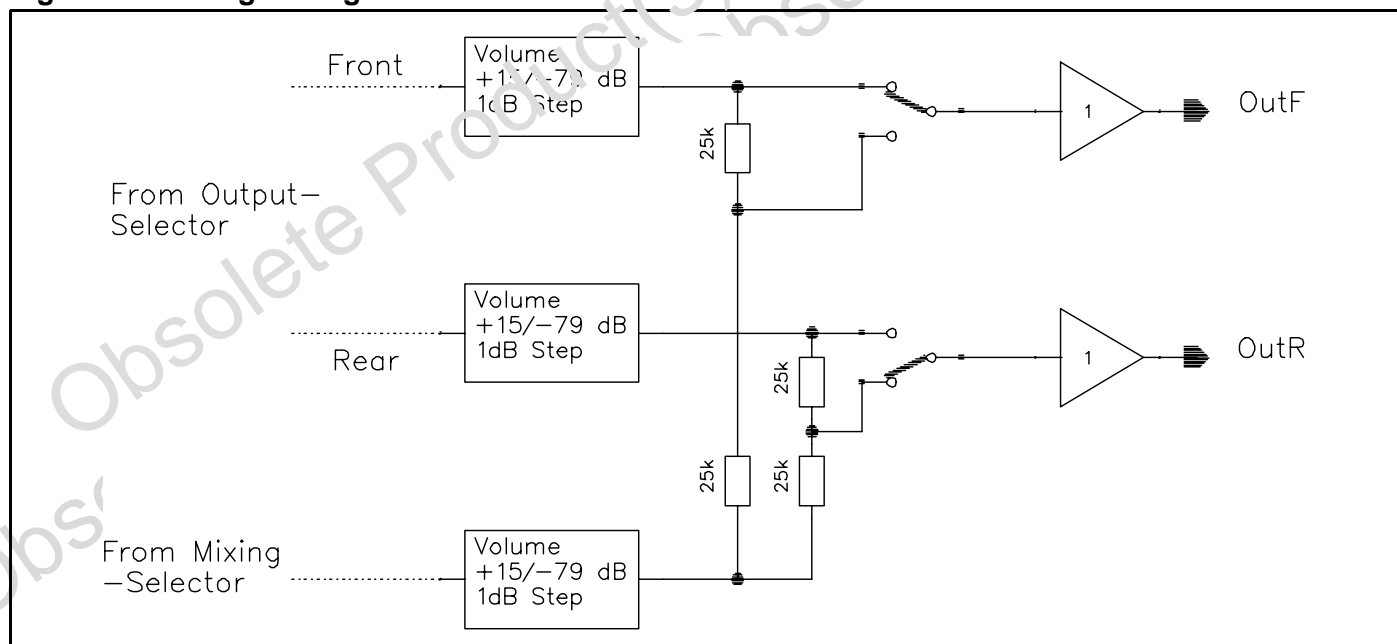

Figure 23. Output Selector

5.10.7 Speaker-Attenuator and Mixing

A Mixing-stage is placed after each speaker-attenuator and can be set independently to mixing-mode. Having a full volume for the Mix-signal the stage offers a wide flexibility to adapt the mixing levels.

Figure 24. Mixing Configuration

5.10.8 Audioprocessor Testing

During the Testmode, which can be activated by setting bit D₀ of the stereodecoder testing-byte and the audio-processor testing byte, several internal signals are available at the FD2R- pin. During this mode the input-resistance of 100kOhm is disconnected from the pin. The internal signals available are shown in the Data-byte specification.

6 STEREODECODER-PART

6.1 Features:

- no external components necessary
- PLL with adjustment free, fully integrated VCO
- automatic pilot dependent MONO/STEREO switching
- very high suppression of intermodulation and interference
- programmable Roll-Off compensation
- dedicated RDS-Softmute
- Highcut- and Stereoblend-characteristics programmable in a wide range
- FM/AMNoiseblanker with several threshold controls
- Multipath-detector with programmable internal/external influence
- I²C-bus control of all necessary functions

Table 7. ELECTRICAL CHARACTERISTICS

V_S = 9V, deemphasis time constant = 50μs, MPX input voltage V_{MPX} = 500mV (75kHz deviation), modulation frequency = 1kHz, input gain = 6dB, T_{amb} = 27°C, unless otherwise specified.

7 NOTES TO THE CHARACTERISTICS

Note 1. Intermodulation Suppression

$$\alpha 2 = \frac{V_o(\text{signal})(\text{at } 1kHz)}{V_o(\text{spurious})(\text{at } 1kHz)}; f_s = (2 \cdot 10kHz) - 19kHz$$

$$\alpha 3 = \frac{V_o(\text{signal})(\text{at } 1kHz)}{V_o(\text{spurious})(\text{at } 1kHz)}; f_s = (3 \cdot 13kHz) - 38kHz$$

measured with: 91% pilot signal; $f_m = 10kHz$ or $13kHz$.

Note 2. Traffic Radio (V.F.) Suppression

measured with: 91% stereo signal; 9% pilot signal; $f_m=1kHz$; 5% subcarrier ($f=57kHz$, $f_m=23Hz$ AM, $m=60\%$)

$$\alpha 57(V.W.F.) = \frac{V_o(\text{signal})(\text{at } 1kHz)}{V_o(\text{spurious})(\text{at } 1kHz \pm 23kHz)}$$

Note 3. SCA (Subsidiary Communications Authorization)

$$\alpha 67 = \frac{V_o(\text{signal})(\text{at } 1kHz)}{V_o(\text{spurious})(\text{at } 9kHz)}; f_s = (3 \cdot 38kHz) - 67kHz$$

measured with: 81% mono signal; 9% pilot signal; $f_m=1kHz$; 10%SCA - subcarrier ($f_s = 67kHz$, unmodulated).

TDA7405

Note 4. ACI (Adjacent Channel Interference)

$$\alpha_{114} = \frac{V_o(\text{signal})(\text{at}1\text{kHz})}{V_o(\text{spurious})(\text{at}4\text{kHz})}; f_s = 110\text{kHz} - (3 \cdot 38\text{kHz})$$

$$\alpha_{190} = \frac{V_o(\text{signal})(\text{at}1\text{kHz})}{V_o(\text{spurious})(\text{at}4\text{kHz})}; f_s = 186\text{kHz} - (5 \cdot 38\text{kHz})$$

measured with: 90% mono signal; 9% pilot signal; fm=1kHz; 1% spurious signal (fs = 110kHz or 186kHz, unmodulated).

8 NOISE BLANKER PART

8.1 Features:

- AM and FM mode
- internal 2nd order 140kHz high-pass filter for MPX path
- internal rectifier and filters for AM-IF path
- programmable trigger thresholds
- trigger threshold dependent on high frequency noise with programmable gain
- additional circuits for deviation- and fieldstrength-dependent trigger adjustment
- 4 selectable pulse suppression times for each mode
- programmable noise rectifier charge/discharge current

Table 8. ELECTRICAL CHARACTERISTICS

10 FUNCTIONAL DESCRIPTION OF STEREODECODER

Figure 29. Blockdiagram of the Stereodecoder

The stereodecoder-part of the A631 (see Figure 28) contains all functions necessary to demodulate the MPX-signal like pilot-tone-dependent MONO/STEREO-switching as well as "stereoblend" and "highcut". Adaptations like programmable input gain, roll-off compensation, selectable deemphasis time constant and a programmable fieldstrength input allow to use different IF-devices.

10.1 Stereodecoder-Mute

The A631 has a fast and easy to control RDS-Mute function which is a combination of the audioprocessor's SoftMute and the high-ohmic mute of the stereodecoder. If the stereodecoder is selected and a SoftMute command is sent (or activated through the SM-pin) the stereodecoder will be set automatically to the high-ohmic mute condition after the audio-signal has been softly muted. Hence a checking of alternate frequencies could be performed. Additionally the PLL can be set to "Hold"-mode, which disables the PLL input during the mute time. To release the system from the mute condition simply the unmute-command must be sent: the stereodecoder is unmuted immediately and the audioprocessor is softly unmuted. Figure 30 shows the output-signal V_O as well as the internal stereodecoder mute signal. This influence of SoftMute on the stereodecoder mute can be switched off by setting bit 3 of the SoftMute byte to "0". A stereodecoder mute command (bit 0, stereodecoder byte set to "1") will set the stereodecoder in any case independently to the high-ohmic mute state.

If any other source than the stereodecoder is selected the decoder remains muted and the MPX-pin is connected to V_{ref} to avoid any discharge of the coupling capacitor through leakage currents. No further mute command should be applied.

Figure 30. Signals during stereodecoder's SoftMute

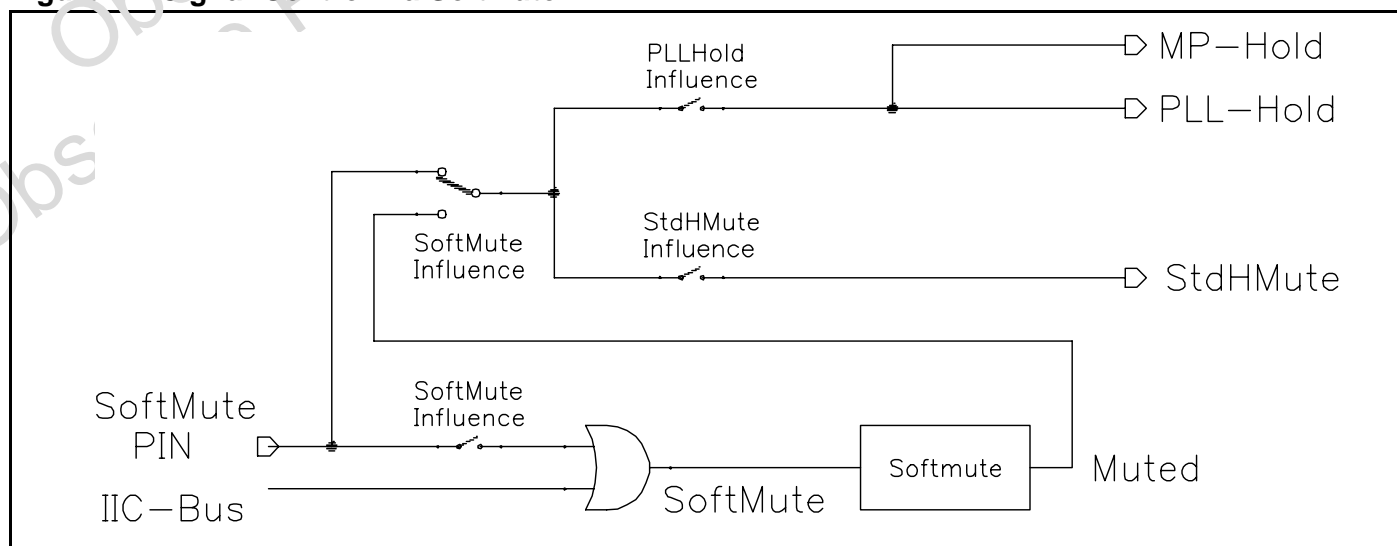

Figure 31. Signal-Control via SoftMute-Pin

TDA7405

10.2 InGain + Infilter

The InGain stage allows to adjust the MPX-signal to a magnitude of about 1V_{rms} internally which is the recommended value. The 4.th order input filter has a corner frequency of 80kHz and is used to attenuate spikes and noise and acts as an anti-aliasing filter for the following switch capacitor filters.

10.3 Demodulator

In the demodulator block the left and the right channel are separated from the MPX-signal. In this stage also the 19-kHz pilotone is cancelled. For reaching a high channel separation the A631 offers an I²C-bus programmable roll-off adjustment which is able to compensate the lowpass behavior of the tuner section. If the tuner's attenuation at 38kHz is in a range from 7.2% to 31.0% the A631 needs no external network in front of the MPX-pin. Within this range an adjustment to obtain at least 40 dB channel separation is possible. The bits for this adjustment are located together with the fieldstrength adjustment in one byte. This gives the possibility to perform an optimization step during the production of the carradio where the channel separation and the fieldstrength control are trimmed. The setup of the Stereoblend characteristics which is programmable in a wide range is described in 2.8.

10.4 Deemphasis and Highcut

The deemphasis-lowpass allows to choose a time constant between 37.5 and 100µs. The highcut control range will be $2 \times t_{\text{Deemp}}$ or $2.7 \times t_{\text{Deemp}}$ dependent on the selected time constant (see programming section). The bit D7 of the highcut-byte will shift timeconstant and range.

Inside the highcut control range (between VHCH and VHCL) the LEVEL signal is converted into a 5 bit word which controls the lowpass time constant between $t_{\text{Deemp}...3}$ ($3.7 \times t_{\text{Deemp}}$). Thereby the resolution will remain always 5 bits independently of the absolute voltage range between the VHCH- and VHCL-values. In addition the maximum attenuation can be fixed between 2 and 10dB.

The highcut function can be switched off by I²C-bus (bit D7, Highcut byte set to "0").

The setup of the highcut characteristics is described in 4.9.

10.5 PLL and Pilotone-Detector

The PLL has the task to lock on the 19kHz pilotone during a stereo-transmission to allow a correct demodulation. The included pilotone-detector enables the demodulation if the pilotone reaches the selected pilotone threshold VPTHST. Two different thresholds are available. The detector output (signal STEREO, see Blockdiagram) can be checked by reading the status byte of the A631 via I²C-bus. During a Softmute the PLL can be set into "Hold"-mode which freezes the PLL's state (bit D4, Softmute byte). After releasing the Softmute the PLL will again follow the input signal only by correcting the phase error.

10.6 Fieldstrength Control

The field strength input is used to control the highcut- and the stereoblend-function. In addition the signal can be also used to control the noiseblanker thresholds and as input for the multipath detector. These additional functions are described in sections 3.3 and 4.

10.7 LEVEL-Input and -Gain

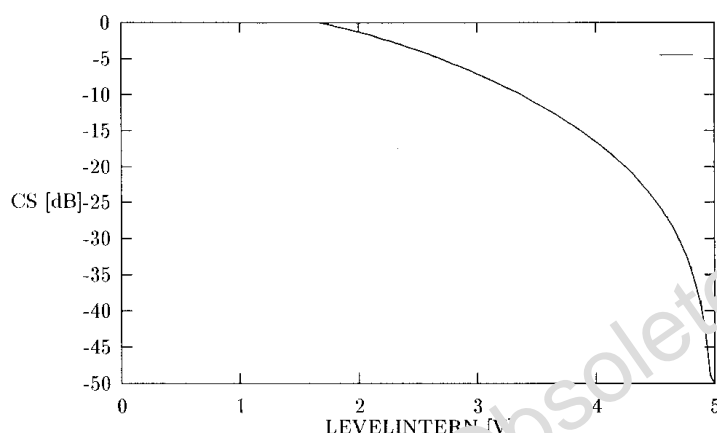

To suppress undesired high frequency modulation on the highcut- and stereoblend-control signal the LEVEL signal is lowpass filtered firstly. The filter is a combination of a 1.st-order RC-lowpass at 53kHz (working as anti-aliasing filter) and a 1.st-order switched-capacitor-lowpass at 2.2kHz. The second stage is a programmable gain stage to adapt the LEVEL signal internally to different IF-devices (see Testmode section 5: LEVELHCC). The gain is widely programmable in 16 steps from 0dB to 6dB (step=0.4dB). These 4 bits are located together with the Roll-Off bits in the "Stereodecoder-Adjustment"-byte to simplify a possible adjustment during the production of the carradio. This signal controls directly the Highcut stage whereas the signal is filtered again ($f_c=100\text{Hz}$) before the stereoblend stage (see Figure 25).

10.8 Stereoblend Control

The stereoblend control block converts the internal LEVEL-voltage (LEVELSB) into an demodulator compatible analog signal which is used to control the channel separation between 0dB and the maximum separation. Internally this control range has a fixed upper limit which is the internal reference voltage REF5V. The lower limit can be programmed between 20 and 70% of REF5V in 3.3% steps (see Figure 31, Figure 29).

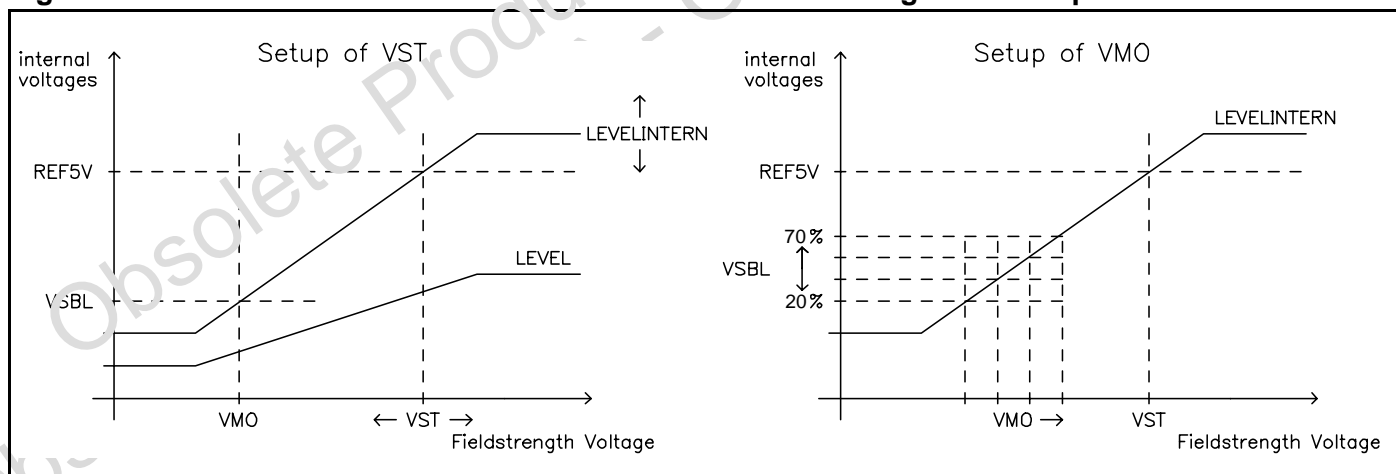

To adjust the external LEVEL-voltage to the internal range two values must be defined: the LEVEL gain LG and VSBL (see Figure 32). At the point of full channel separation the external level signal has to be amplified that internally it becomes equal to REF5V. The second point (e.g. 10dB channel sep.) is then adjusted with the VSBL voltage.

Figure 32. Internal stereoblend characteristics

The gain can be programmed through 4 bits in the "Stereodecoder-Adjustment"-byte. All necessary internal reference voltages like REF5V are derived from a bandgap circuit. Therefore they have a temperature coefficient near zero.

Figure 33. Relation between internal and external LEVEL-voltages for setup of Stereoblend

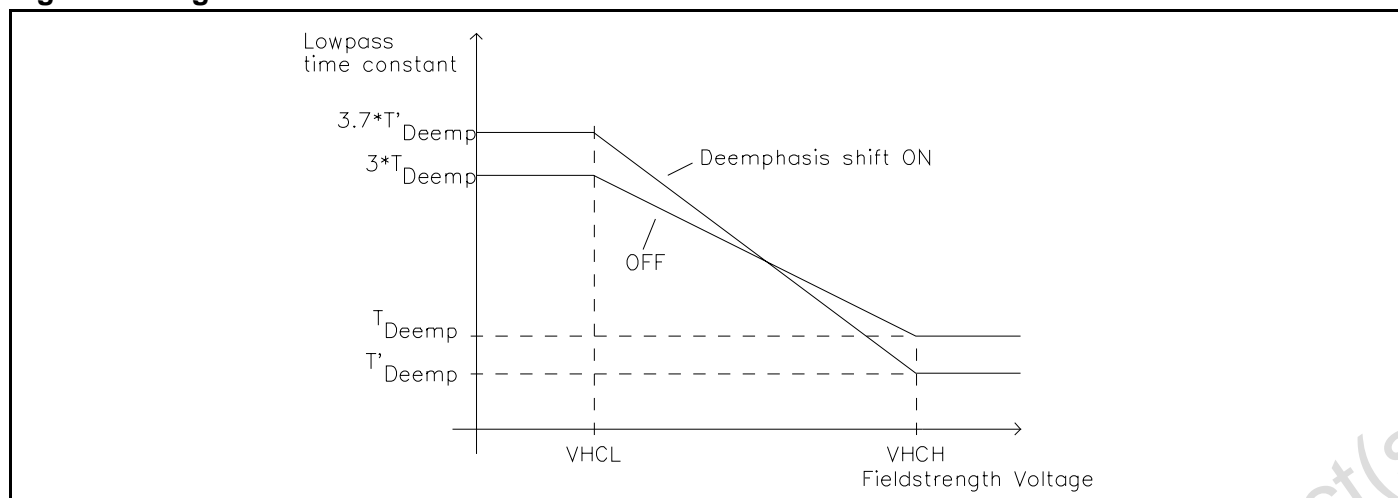

10.9 Highcut Control

The highcut control setup is similar to the stereoblend control setup : the starting point VHCH can be set with 2 bits to be 42, 50, 58 or 66% of REF5V whereas the range can be set to be 17, 22, 28 or 33% of VHCH (see Figure 30).

TDA7405

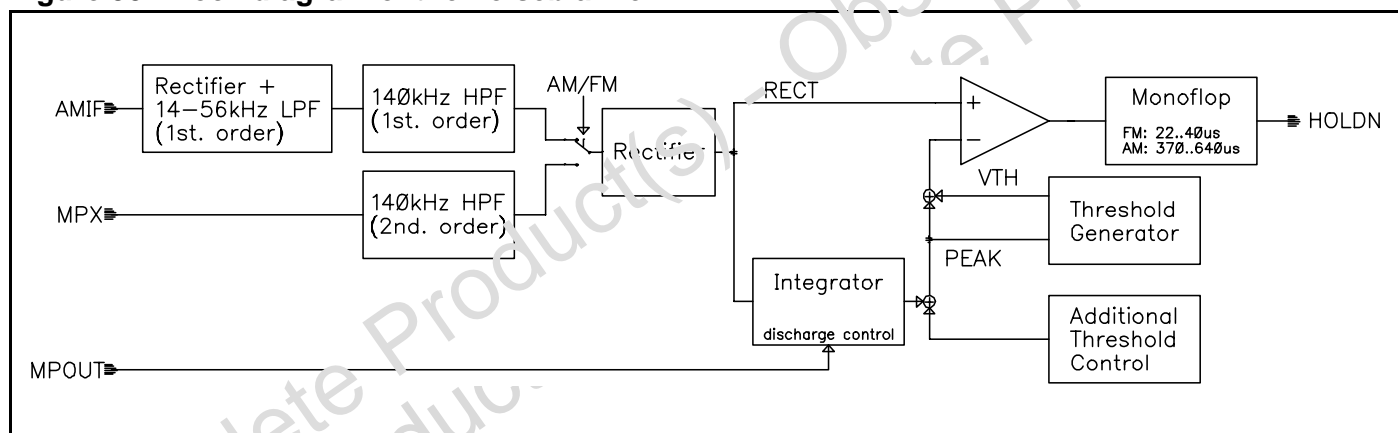

Figure 34. Highcut characteristics

11 FUNCTIONAL DESCRIPTION OF THE NOISEBLANKER

In the automotive environment the MPX-signal as well as the AM-signal is disturbed by spikes produced by the ignition and other radiating sources like the wiper-motor. The aim of the noiseblanker part is to cancel the audible influence of the spikes. Therefore the output of the stereodecoder is held at the actual voltage for a time between 22 and 38µs in FM (370 and 645µs in AM-mode). The blockdiagram of the noiseblanker is given in Figure 34.

Figure 35. Block diagram of the noiseblanker

In a first stage the spikes must be detected but to avoid a wrong triggering on high frequency (white) noise a complex trigger control is implemented. Behind the triggerstage a pulse former generates the "blanking"-pulse.

11.1 Trigger Path FM

The incoming MPX signal is highpass-filtered, amplified and rectified. This second order highpass-filter has a corner-frequency of 140kHz. The rectified signal, RECT, is integrated (lowpass filtered) to generate a signal called PEAK. The DC-charge/discharge behaviour can be adjusted as well as the transient behaviour (MP-discharge control). Also noise with a frequency 140kHz increases the PEAK voltage. The PEAK voltage is fed to a threshold generator, which adds to the PEAK-voltage a DC-dependent threshold VTH. Both signals, RECT and PEAK+VTH are fed to a comparator which triggers a re-triggerable monoflop. The monoflop's output activates the sample-and-hold circuits in the signalpath for the selected duration

11.2 Noise Controlled Threshold Adjustment (NCT)

There are mainly two independent possibilities for programming the trigger threshold:

1. the low threshold in 8 steps (bits D₁ to D₃ of the noiseblanker-byte I)
2. and the noise adjusted threshold in 4 steps (bits D₄ and D₅ of the noiseblanker-byte I, see Figure 22).

The low threshold is active in combination with a good MPX signal without noise; the PEAK voltage is less than 1V. The sensitivity in this operation is high. If the MPX signal is noisy (low fieldstrength) the PEAK voltage increases due to the higher noise, which is also rectified. With increasing of the PEAK voltage the trigger threshold increases, too. This gain is programmable in 4 steps (see Figure 25).

11.3 Additional Threshold Control Mechanism

11.3.1 Automatic Threshold Control by the Stereoblend voltage

Besides the noise controlled threshold adjustment there is an additional possibility for influencing the trigger threshold which depends on the stereoblend control.

The point where the MPX signal starts to become noisy is fixed by the RF part. Therefore also the starting point of the normal noise-controlled trigger adjustment is fixed (Figure 27). In some cases the behavior of the noise-blanker can be improved by increasing the threshold even in a region of higher fieldstrength. Sometimes a wrong triggering occurs for the MPX signal often shows distortion in this range which can be avoided even if using a low threshold. Because of the overlap of this range and the range of the stereo/mono transition it can be controlled by stereoblend. This increase of the threshold is programmable in 3 steps or switched off.

11.3.2 Over Deviation Detector

If the system is tuned to stations with a high deviation the noiseblanker can trigger on the higher frequencies of the modulation or distortion. To avoid this behavior, which causes audible noise in the output signal, the noiseblanker offers a deviation-dependent threshold adjustment. By rectifying the MPX signal a further signal representing the actual deviation is obtained. It is used to increase the PEAK voltage. Offset and gain of this circuit are programmable in 3 steps with the bits D₆ and D₇ of the noiseblanker-byte I (bit combination '00' turns off the detector, see Figure 26).

11.3.3 Multipath-Level

To react on high repetitive spikes caused by a Multipath-situation, the discharge-time of the PEAK voltage can be decreased depending on the voltage-level at pin MPout. The A631 offers a linear as well as a threshold driven control. The linear influence of the Multipath-Level on the PEAK-signal (D₇ of Multipath-Control-Byte) gives a discharge slewrates of 1V/ms¹. The second possibility is to activate the threshold driven discharge which switches on the 18kOhm discharge if the Multipath-Level is below 2.5V (D₇ of noiseblanker-byte II-byte).

¹ The slewrates is measured with R_{Discharge} = infinite and V_{MPout} = 2.5V

11.3.4 AM mode of the Noiseblanker

The A631 noiseblanker is also suitable for AM noise canceling. The detector uses in AM mode the 450kHz unfiltered IF-output of the tuner for spike detection. A combination of programmable gain-stage and lowpass-filter forms an envelope detector which drives the noiseblanker's input via a 120 kHz 1st order highpass. In order to blank the whole spike in AM mode the hold-times of the sample and hold circuit are much longer then in FM (640µs to 1.2ms). All threshold controls can be used like in FM mode.

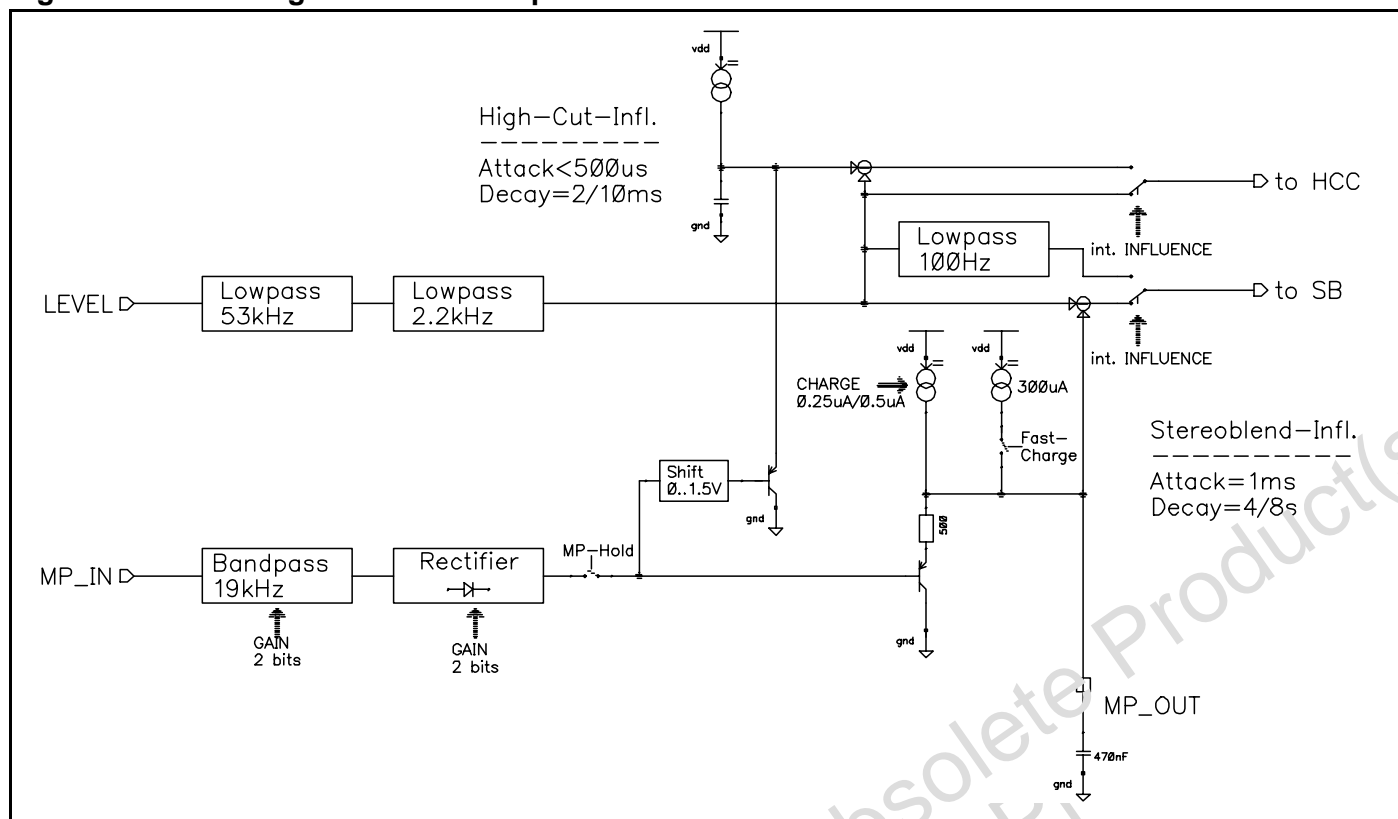

11.4 Functional Description of the Multipath-Detector

Using the Multipath-Detector the audible effects of a multipath condition can be minimized. A multipath-condition is detected by rectifying the spectrum around 19kHz in the fieldstrength signal. An external capacitor is used to define the attack- and decay-times for the Stereoblend (see blockdiagram, Figure 35). Due to the very small charge currents this capacitor should be a low leakage current type (e.g. ceramic). Using this configuration an adaptation to the user's requirement is possible without effecting the "normal" fieldstrength input (LEVEL) for the stereodecoder. This application is given in Figure 35. Another (internal) time constant is used to control the Highcut through the multipath detector

Selecting the "internal influence" in the configuration byte the Stereo-Blend and/or the Highcut is automatically invoked during a multipath condition according to the voltage appearing at the MP_OUT-pin.

TDA7405

Figure 36. Blockdiagram of the Multipath-Detector

11.5 Quality Detector

The TDA7405 offers a quality detector output which gives a voltage representing the FM-reception conditions. To calculate this voltage the MPX-noise and the multipath-detector output are summed according to the following formula :

$$V_{Qual} = 1.5 (V_{Noise} - 0.8 V) + a (REF5V - V_{Mpout}).$$

The noise-signal is the PEAK-signal without additional influences (see noiseblanker description). The factor 'a' can be programmed to 0.7 ... 1.15. The output is a low impedance output able to drive external circuitry as well as simply fed to an AD converter for RDS applications.

11.6 Dual-MPX Mode

The TDA7405 is able to support a twin tuner concept via the Dual-MPX-Mode. In this configuration the MPX-pin and the MD2G-pin are acting as MPX1 and MPX2 inputs. The DC-Voltage at the MD2-pin controls whether one or both MPX-signals are used to decode the stereo FM-signal. It is designed as a window-comparator with the characteristic shown in Figure 36 (Please note that the thresholds have a hysteresis of 500mV). In this mode the stereodecoder highohmic-mute mutes both inputs in parallel.

Figure 37. Blockdiagram Dual MPX

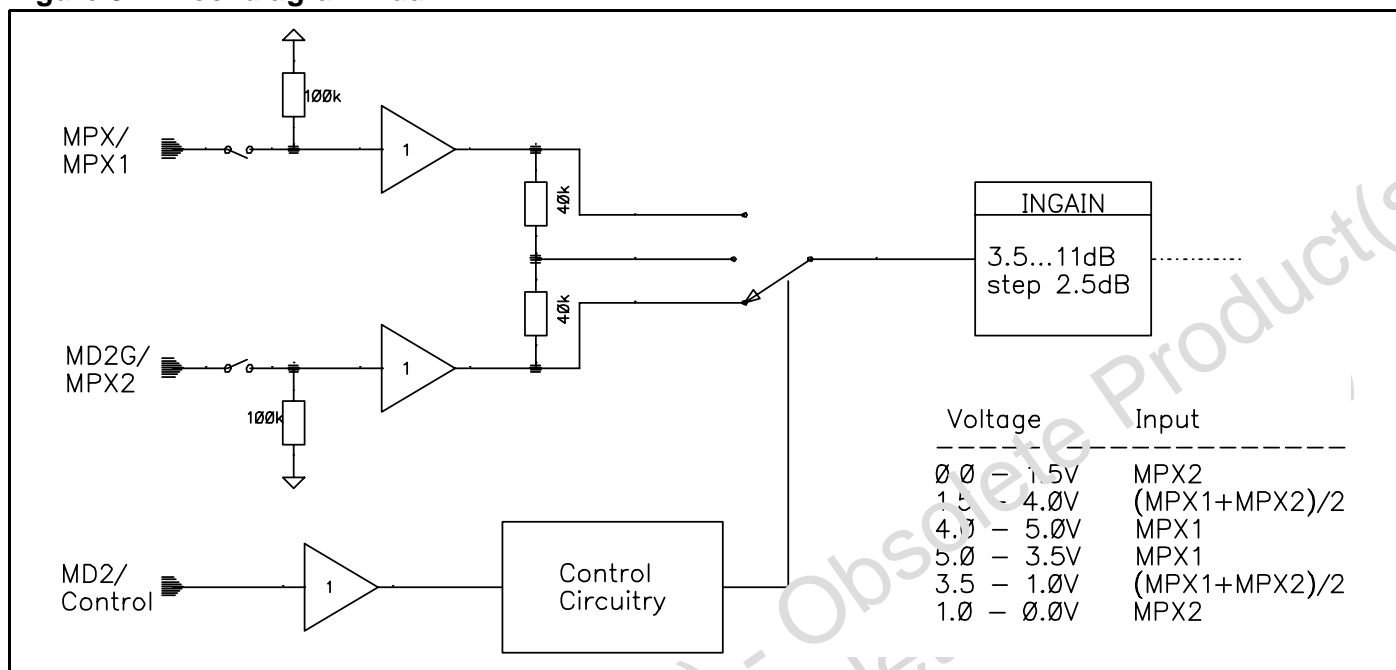

Table 10. Pin-Configuration DMPX-/WSM-Mode

Dual MPX	Weak-Signal Mute	AMIF (12)	DMPXC(25)	MPX2(26)	MD2(43)	MD2G(44)
off	off	AMIF-In	not used	not used	MD2-In	MD2-Gnd
off	on	WSM-TC	WSM-In	WSM-Out	MD2-In	MD2-Gnd
on	off	AMIF-In	DMPC-Cntrl	MPX2	MD2-In	MD2-Gnd
on	on	WSM-TC	WSM-In	WSM-Out	DMPC-Cntrl	MPX2

11.7 Weak-Signal Mute

For use with front-ends which do not support a weak-signal-mute function the TDA7405 offers this feature as well. If this mode is enabled the pins 29 and 30 are used as an AC-coupling behind the Mute-Stage (see block-diagram). In parallel pin 12 (AMIF) is switched internally to realize a mute time-constant with fast attack- and slow decay-time.

TDA7405

Figure 38. Weak-Signal Mute-Depth @ 0.5V Threshold

Figure 39. Weak-Signal Mute-Threshold @ 24dB Mute-Depth

11.8 Stereodecoder Testmode

During the Testmode, which can be activated by setting bit D0 and bit D1 of the stereodecoder testing-byte, several internal signals are available at the FD2R+ pin. During this mode the input resistance of 100kOhm is disconnected from the pin. The internal signals available are shown in the Data-byte specification.

12 I²C BUS INTERFACE

12.1 Interface Protocol

The interface protocol comprises:

- a start condition (S)
- a chip address byte (the LSB bit determines read / write transmission)
- a subaddress byte
- a sequence of data (N-bytes + acknowledge)
- a stop condition (P)

S = Start

R/W = "0" -> Receive-Mode (Chip could be programmed by μ P)

"1" -> Transmission-Mode (Data could be received by μ P)

ACK = Acknowledge

P = Stop

MAX CLOCK SPEED 500kbts/s

12.1.1 Auto increment

If bit I in the subaddress byte is set to "1", the autoincrement of the subaddress is enabled.

12.1.2 TRANSMITTED DATA (send mode)

MSB						LSB	
X	X	X	X	X	P	ST	SM

SM = Soft mute activated

ST = Stereo

P = Pause

X = Not Used

The transmitted data is automatically updated after each ACK. Transmission can be repeated without new chip address.

12.1.3 Reset Condition

A Power-On-Reset is invoked if the Supply-Voltage is below than 3.5V. After that the following data is written automatically into the registers of all subaddresses :

MSB							LSB
1	1	1	1	1	1	1	0

The programming after POR is marked bold-face / underlined in the programming tables.

With this programming all the outputs are muted to V_{REF} ($V_{OUT} = V_{DD}/2$).
