Single-Inductor, Multiple-Output (SIMO) Regulator for AMOLED

FEATURES

- 2.3-V to 5.5-V Input Voltage Range
- 1% Output Voltage Accuracy
- Low-Noise Operation
- 750-mW Output Power at $V_{in} = 2.9\text{ V}$
- SIMO Regulator Technology
- Fixed 4.6-V Positive Output Voltage
- Negative Output Voltage Down to -6 V
- Advanced Power-Save Mode for Light-Load Efficiency

- Out-of-Audio Mode
- Short-Circuit Protection
- Excellent Line Regulation
- Thermal Shutdown
- 3-mm x 3-mm Thin QFN Package

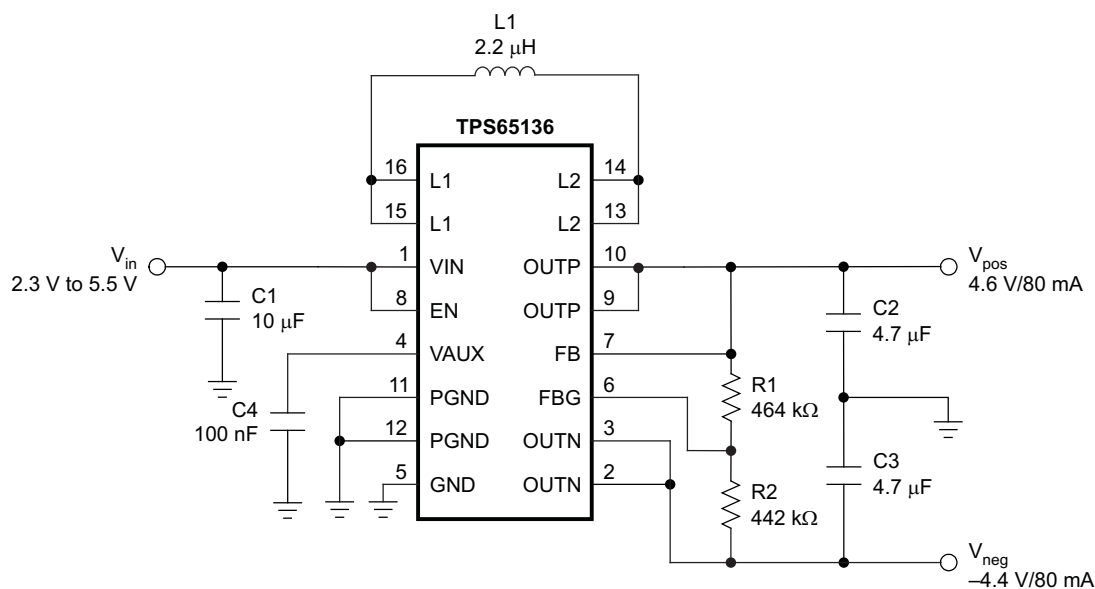

APPLICATIONS

- Active-Matrix OLED Power Supply

DESCRIPTION

The TPS65136 is designed to provide best-in-class picture quality for active-matrix OLED (AMOLED) displays that require positive and negative supply rails. With its wide input voltage range, the device is ideally suited for AMOLED displays, which are used in mobile phones or SmartPhone™ devices. With the new single-inductor multiple-output (SIMO) technology, the smallest possible solution size is achieved. The device operates with a buck-boost topology and generates both positive and negative output voltages above or below the input voltage rail. The SIMO technology enables excellent line and load regulation. Excellent line-transient regulation is required to avoid disturbance of the AMOLED display as a result of input voltage variations that occur during transmit periods in mobile communication systems.

DETAILED DESCRIPTION

The TPS65136 operates with a four-switch buck-boost converter topology, generating a negative and a positive output voltage with a single inductor. The device uses the SIMO regulator technology featuring best-in-class line-transient regulation, buck-boost mode for the positive and negative outputs, and highest efficiency over the entire load-current range. High efficiency over the entire load-current range is implemented by reducing the converter switching frequency. Out-of-audio mode avoids the switching frequency going below 20 kHz.

As illustrated in the [functional block diagram](#), the converter operates with two control loops. One error amplifier sets the output voltage for the positive output, OUTP. The ground error amplifier regulates FBG to typically 0 V. Using the external feedback divider allows setting the output voltage of the negative output, OUTN. In principle, the converter topology operates just like any other buck-boost converter topology with the difference that the output voltage across the inductor is the sum of the positive and negative output voltages. With this consideration, all calculations of the buck-boost converter apply for this topology as well. During the first switch cycle, M1 and M2 are closed, connecting the inductor from VIN to GND. During the second switch cycle, the inductor discharges to the positive and negative outputs by closing switches M4 and M3. Because the inductor is discharged to both of the outputs simultaneously, the output voltages can be higher or lower than the input voltage. In addition to that, the converter operates best when the current out of OUTP is equal to the current flowing into OUTN. This is usually the case when driving an AMOLED panel. Any asymmetries in load current can be canceled out by the ground error amplifier connected to FBG. However, this is only possible for current asymmetries of typically 30%. During light load current in discontinuous conduction mode, the converter operates in peak-current-mode control with the switching cycle given by the internal voltage-controlled oscillator (VCO). As the load current increases, the converter operates in continuous-conduction mode. In this mode, the converter moves to peak-current control with the switch cycle given by the fixed off-time. The SIMO regulator topology has excellent line transient regulation when operating in discontinuous conduction mode. As the load current increases, entering continuous conduction mode, the line transient performance is linearly decreased.

TPS65136

SLVS831A–APRIL 2008–REVISED JULY 2008

www.ti.com

Advanced Power-Save Mode for Light-Load Efficiency

In order to maintain high efficiency over the entire load-current range, the converter reduces its switching frequency as the load current decreases. The advanced power-save mode controls the switching frequency using a voltage-controlled oscillator (VCO). The VCO frequency is proportional to the inductor peak current, with a lower frequency limit of 20 kHz. This avoids disturbance of the audio band and minimizes audible noise coming from the ceramic input and output capacitors. By maintaining a controlled switching frequency, possible EMI is minimized. This is especially important when using the device in mobile phones. See Figure 8 for typical switching frequency versus load current.

Buck-Boost Mode Operation

Buck-boost mode operation allows the input voltage to be higher than the output voltage. This mode allows the use of batteries and supply voltages that are above the fixed 4.6-V output voltage of OUTP.

Inherent Excellent Line-Transient Regulation

The SIMO regulator achieves inherent superior line-transient regulation when operating in discontinuous conduction mode, shown in Figure 5 and Figure 6. In discontinuous conduction mode, the current delivered to the output is given by the inductor peak current and falling slope of the inductor current. This is shown in Figure 14, where the output current, given by the area A, is the same for different input voltages. Because the converter uses peak-current-mode control, the peak current is fixed as long as the load current is fixed. The falling slope of the inductor current is given by the sum of the output voltage and inductor value. This is also a fixed value and independent of the input voltage. Because of this, any change in input voltage changes the converter duty cycle but does not change the inductor peak current or the falling slope of the inductor current. Therefore, the output current, given by the area A (Figure 14), remains constant over any input voltage variation. Because the area A is constant, the converter has an inherently perfect line regulation when operating in discontinuous conduction mode. Entering continuous conduction mode (CCM) linearly decreases the line-transient performance. However, the line-transient response in CCM is still as good as for any standard current-mode-controlled switching converter. The following formulas detail the relations of the TPS65136 converter topology operating in CCM.

Figure 14. Inherently Perfect Line-Transient Regulation

The converter always sees the sum of the negative and positive output voltage, which is calculated as:

$$V_o = V_{outp} + |V_{outn}|$$

The converter duty cycle is calculated using the efficiency estimation from the data sheet curves or from real application measurements. A 70% efficiency value is a good value to go through the calculations.

$$D = \frac{V_o}{V_{in} \cdot \eta + V_o}$$

The output current for entering continuous conduction mode can be calculated. The switching frequency can be obtained from the data sheet graphs. A frequency of 1.5 MHz is usually sufficient for these types of calculations.

$$I_c = \frac{V_o \cdot (1-D)^2}{f_s \cdot 2 \cdot L} \quad (1)$$

The inductor ripple current when operating in CCM can also be calculated.

$$\Delta i_L = \frac{V_{in} \cdot D}{L \cdot f_s}$$

Last but not least, the converter switch peak current is calculated.

$$I_{sw} = \frac{V_{in} \cdot D}{2 \cdot f \cdot L} + \frac{I_{out}}{1-D} \quad (2)$$

Overvoltage Protection

The device monitors both the positive and negative output voltages. The positive regulator monitors the positive output and reduces the current limit when the output voltage exceeds the overvoltage protection limit. The negative output is clamped using a zener diode, typically to -7.6 V.

Short-Circuit Protection

Both outputs are protected against short circuits either to GND or against the other output. For the positive output, the device switching frequency and the current limit are reduced in case of a short circuit.

Soft-Start Operation

The device increases the current limit during soft-start operation to avoid high inrush currents during start-up. The current limit typically ramps up to its full-current limit within $100 \mu\text{s}$.

Start-Up Sequencing

The TPS65136 includes an internal, fixed start-up sequence, where the negative output voltage rail comes up after the positive output voltage rail. The device starts the positive rail first, and an internal counter delays the start-up of the negative rail, typically by 8.7 ms. The negative rail is clamped, typically to -0.4 V, until the internal timer commands the negative rail to start up.

T0298-01

Figure 15. Start-Up Sequencing

Output-Current Mismatch

The device operates best when the current of the positive output is similar to the current of the negative output. However, the device is able to regulate an output-current mismatch between the outputs of up to 30%. If the output-current mismatch becomes much larger, then one of the outputs goes out of regulation.

Input Capacitor Selection

The device typically requires a $10\text{-}\mu\text{F}$ ceramic input capacitor. Larger values can be used to lower the input voltage ripple. [Table 1](#) lists capacitors suitable for use on the TPS65136 input.

TPS65136

SLVS831A–APRIL 2008–REVISED JULY 2008

www.ti.com

Table 1. Input Capacitor Selection

10 μ F/6.3 V	Taiyo Yuden JMK107BJ106	0603

Inductor Selection/Efficiency/Line-Transient Response

The device is internally compensated and provides stable operation with either a 4.7- μ H or 2.2- μ H inductor. For this type of converter, the inductor selection is a key element in the design process, because it has an impact on several application parameters. The inductor selection influences the converter efficiency, line transient response, and maximum output current. Because the inductor ripple current is fairly large in this type of application, the inductor has a major impact on the overall converter efficiency. Having large inductor ripple current causes the inductor core and magnetizing losses to become dominant. Due to this, an inductor with a larger dc winding resistance can possibly achieve higher converter efficiencies when having lower core and magnetizing losses. Therefore, minimizing inductor ripple current also increases the overall converter efficiency. A 4.7- μ H inductor achieves a higher efficiency compared to a 2.2- μ H inductor, due to lower inductor ripple current. The inductor value also influences the line transient regulation. This is because the inductor value influences the current range entering continuous conduction mode (CCM). As discussed, the line transient performance decreases when entering CCM. The larger the inductor value, the lower the load current when entering CCM. The formula to calculate the current entering CCM is shown in [Equation 1](#). The inductors listed in [Table 2](#) achieve a good overall converter efficiency while having a low device profile of just 0,8 mm. The inductor saturation current should be 900 mA, depending on the maximum output current of the application. See [Equation 2](#), where the converter switch current limit is calculated. The converter switch current is equal to the peak inductor current.

Table 2. Inductor Selection

INDUCTOR VALUE	COMPONENT SUPPLIER	DIMENSIONS in mm	I _{sat} /DCR
2.2 μ H	Coilcraft LPS3008-222	2,95 × 2,95 × 0,8	1.1 A/175 m Ω

2.2 μ H	Maruwa CXFU0208-2R2	2,65 × 2,65 × 0,8	0.85A/185 m Ω
4.7 μ H	Maruwa CXFU0208-4R7	2,65 × 2,65 × 0,8	0.51A/440 m Ω
4.7 μ H	Coilcraft LPS3008-472	2,95 × 2,95 × 0,8	0.8 A/350 m Ω
4.7 μ H	ABCO LPF3010T-4R7	2,8 × 2,8 × 1	0.7A/280 m Ω

Output Capacitor Selection

A 4.7- μ F output capacitor is generally sufficient for most applications, but larger values can be used as well for improved line-transient response at higher load currents. The capacitor of [Table 3](#) is recommended for use with the TPS65136.

Table 3. Output Capacitor Selection

CAPACITOR	COMPONENT SUPPLIER	SIZE
4.7 μ F/10V	Taiyo Yuden LMK107BJ475	0603

Setting the Negative Output Voltage OUTN

For highest output-voltage accuracy, the TPS65136 has an internally fixed output voltage for the positive output. The negative output voltage is adjustable. Because the feedback FBG is regulated to ground, the voltage across R1 is equal to the positive output voltage of 4.6 V. R1 is selected to have at least 10 μ A through the feedback divider.

$$R1 = \frac{4.6 \text{ V}}{10 \mu\text{A}} \approx 464 \text{ k}\Omega$$

R2 is then calculated as:

$$R2 = \frac{|V_{\text{neg}}|}{4.6 \text{ V}} \times R1$$

PCB Layout Guidelines

PCB layout is an important task in the power supply design. Good PCB layout minimizes EMI and allows very good output voltage regulation. For the TPS65136, the following PCB layout guidelines are recommended.

Place the power components first. The inductor and the input and output capacitors must be as close as possible to the IC pins. Place the bypass capacitor for the reference output voltage VAUX as close as possible to pin 4. Use bold and wide traces for power traces connecting the inductor and input and output capacitors. Use a common ground plane or a start ground connection.

See the TPS65136EVM-063 user's guide ([SLVU244](#)) and evaluation module for a PCB layout example.

PACKAGING INFORMATION

Orderable Device	Status (1)	Package Type	Package Drawing	Pins	Package Qty	Eco Plan (2)	Lead/Ball Finish	MSL Peak Temp (3)	Op Temp (°C)	Top-Side Markings (4)	Samples
TPS65136RTER	ACTIVE	WQFN	RTE	16	3000	Green (RoHS & no Sb/Br)	CU NIPDAU	Level-2-260C-1 YEAR	-40 to 85	CCO	
TPS65136RTERG4	ACTIVE	WQFN	RTE	16	3000	Green (RoHS & no Sb/Br)	CU NIPDAU	Level-2-260C-1 YEAR	-40 to 85	CCO	

(1) The marketing status values are defined as follows:

ACTIVE: Product device recommended for new designs.

LIFEBUY: TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.

NRND: Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.

PREVIEW: Device has been announced but is not in production. Samples may or may not be available.

OBSOLETE: TI has discontinued the production of the device.

(2) Eco Plan - The planned eco-friendly classification: Pb-Free (RoHS), Pb-Free (RoHS Exempt), or Green (RoHS & no Sb/Br) - please check <http://www.ti.com/productcontent> for the latest availability information and additional product content details.

TBD: The Pb-Free/Green conversion plan has not been defined.

Pb-Free (RoHS): TI's terms "Lead-Free" or "Pb-Free" mean semiconductor products that are compatible with the current RoHS requirements for all 6 substances, including the requirement that lead not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, TI Pb-Free products are suitable for use in specified lead-free processes.

Pb-Free (RoHS Exempt): This component has a RoHS exemption for either 1) lead-based flip-chip solder bumps used between the die and package, or 2) lead-based die adhesive used between the die and leadframe. The component is otherwise considered Pb-Free (RoHS compatible) as defined above.

Green (RoHS & no Sb/Br): TI defines "Green" to mean Pb-Free (RoHS compatible), and free of Bromine (Br) and Antimony (Sb) based flame retardants (Br or Sb do not exceed 0.1% by weight in homogeneous material)

(3) MSL, Peak Temp. -- The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

(4) Multiple Top-Side Markings will be inside parentheses. Only one Top-Side Marking contained in parentheses and separated by a "-" will appear on a device. If a line is indented then it is a continuation of the previous line and the two combined represent the entire Top-Side Marking for that device.

THERMAL INFORMATION

This package incorporates an exposed thermal pad that is designed to be attached directly to an external heatsink. The thermal pad must be soldered directly to the printed circuit board (PCB). After soldering, the PCB can be used as a heatsink. In addition, through the use of thermal vias, the thermal pad can be attached directly to the appropriate copper plane shown in the electrical schematic for the device, or alternatively, can be attached to a special heatsink structure designed into the PCB. This design optimizes the heat transfer from the integrated circuit (IC).

For information on the Quad Flatpack No-Lead (QFN) package and its advantages, refer to Application Report, QFN/SON PCB Attachment, Texas Instruments Literature No. SLUA271. This document is available at www.ti.com.

IMPORTANT NOTICE

Texas Instruments Incorporated and its subsidiaries (TI) reserve the right to make corrections, enhancements, improvements and other changes to its semiconductor products and services per JESD46, latest issue, and to discontinue any product or service per JESD48, latest issue. Buyers should obtain the latest relevant information before placing orders and should verify that such information is current and complete. All semiconductor products (also referred to herein as "components") are sold subject to TI's terms and conditions of sale supplied at the time of order acknowledgment.

TI warrants performance of its components to the specifications applicable at the time of sale, in accordance with the warranty in TI's terms and conditions of sale of semiconductor products. Testing and other quality control techniques are used to the extent TI deems necessary to support this warranty. Except where mandated by applicable law, testing of all parameters of each component is not necessarily performed.

TI assumes no liability for applications assistance or the design of Buyers' products. Buyers are responsible for their products and applications using TI components. To minimize the risks associated with Buyers' products and applications, Buyers should provide adequate design and operating safeguards.

TI does not warrant or represent that any license, either express or implied, is granted under any patent right, copyright, mask work right, or other intellectual property right relating to any combination, machine, or process in which TI components or services are used. Information published by TI regarding third-party products or services does not constitute a license to use such products or services or a warranty or endorsement thereof. Use of such information may require a license from a third party under the patents or other intellectual property of the third party, or a license from TI under the patents or other intellectual property of TI.

Reproduction of significant portions of TI information in TI data books or data sheets is permissible only if reproduction is without alteration and is accompanied by all associated warranties, conditions, limitations, and notices. TI is not responsible or liable for such altered documentation. Information of third parties may be subject to additional restrictions.

Resale of TI components or services with statements different from or beyond the parameters stated by TI for that component or service voids all express and any implied warranties for the associated TI component or service and is an unfair and deceptive business practice. TI is not responsible or liable for any such statements.

Buyer acknowledges and agrees that it is solely responsible for compliance with all legal, regulatory and safety-related requirements concerning its products, and any use of TI components in its applications, notwithstanding any applications-related information or support that may be provided by TI. Buyer represents and agrees that it has all the necessary expertise to create and implement safeguards which anticipate dangerous consequences of failures, monitor failures and their consequences, lessen the likelihood of failures that might cause harm and take appropriate remedial actions. Buyer will fully indemnify TI and its representatives against any damages arising out of the use of any TI components in safety-critical applications.

In some cases, TI components may be promoted specifically to facilitate safety-related applications. With such components, TI's goal is to help enable customers to design and create their own end-product solutions that meet applicable functional safety standards and requirements. Nonetheless, such components are subject to these terms.

No TI components are authorized for use in FDA Class III (or similar life-critical medical equipment) unless authorized officers of the parties have executed a special agreement specifically governing such use.

Only those TI components which TI has specifically designated as military grade or "enhanced plastic" are designed and intended for use in military/aerospace applications or environments. Buyer acknowledges and agrees that any military or aerospace use of TI components which have **not** been so designated is solely at the Buyer's risk, and that Buyer is solely responsible for compliance with all legal and regulatory requirements in connection with such use.

TI has specifically designated certain components as meeting ISO/TS16949 requirements, mainly for automotive use. In any case of use of non-designated products, TI will not be responsible for any failure to meet ISO/TS16949.
