MIDRANGE INPUT SYNCHRONOUS BUCK CONTROLLER WITH VOLTAGE FEED-FORWARD

FEATURES

- Operation Over 4.5-V to 28-V Input Range
- Fixed-Frequency Voltage-Mode Controller
- Integrated Unity Gain Amplifier for Remote Output Sensing
- Predictive Gate Drive™ Generation II for Improved Efficiency
- <1% Internal 700-mV Reference
- Input Voltage Feed Forward Control
- Prebiased Output Compatible
- Internal Gate Drive Outputs for High-Side and Synchronous N-Channel MOSFETs
- Switching Frequency Programmable to 1 MHz
- 20-Pin QFN Package
- Thermal Shutdown Protection
- Software Design Tool and EVM Available

APPLICATIONS

- Power Modules
- Networking/Telecom
- Industrial
- Servers

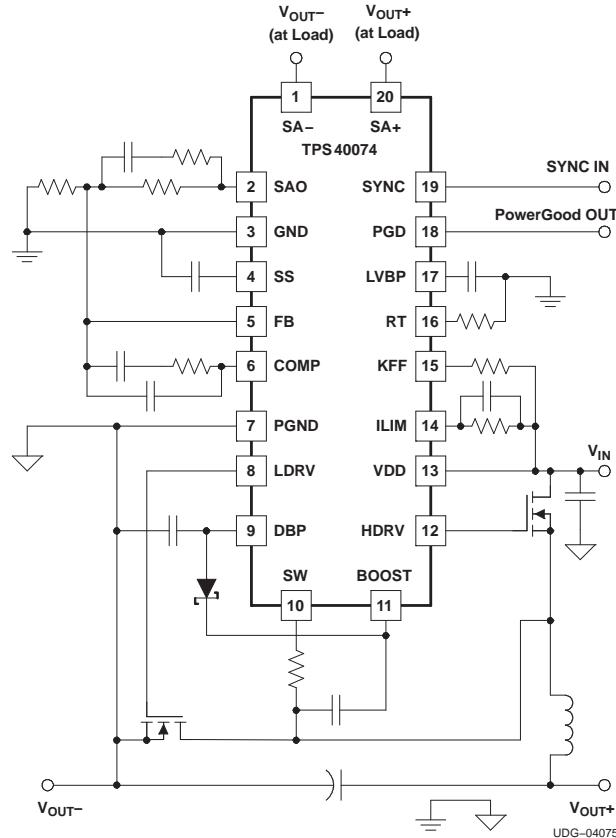

DESCRIPTION

The TPS40074 is a mid voltage, wide input (4.5-V to 28-V), synchronous, step-down controller, offering design flexibility for a variety of user programmable functions, including; soft start, UVLO, operating frequency, voltage feed-forward and high-side FET sensed short circuit protection.

The TPS40074 incorporates MOSFET gate drivers for external N-channel high side and synchronous rectifier (SR) MOSFETs. The gate drive logic incorporates second generation predictive anti-cross conduction circuitry to prevent simultaneous high side and synchronous rectifier conduction, while minimizing to eliminating current flow in the body diode of the SR FET. The TPS40074 allows for starting into pre-biased outputs by not allowing the synchronous rectifier FET to turn on until the commanded voltage during soft start is greater than the existing pre-bias voltage.

The TPS40074 uses voltage feed-forward control techniques to provide good line regulation over a wide input voltage range, and fast response to input line transients. Voltage feed-forward also provides nearly constant power stage gain with input variation to ease loop compensation of wide input range designs. The externally programmable short circuit protection provides fault current limiting, as well as hiccup mode operation for low power dissipation in the presence of a shorted output. The TPS40074 is packaged in a 20-pin QFN package for better thermal performance at higher voltages and frequencies, as well as reduced footprint.

SIMPLIFIED APPLICATION DIAGRAM

Please be aware that an important notice concerning availability, standard warranty, and use in critical applications of Texas Instruments semiconductor products and disclaimers thereto appears at the end of this data sheet.

TPS40074
SLUS617B-APRIL 2005-REVISED OCTOBER 2006
Table 1. TERMINAL FUNCTIONS

TERMINAL NAME NO.	I/O	DESCRIPTION
BOOST 11	I	The BOOST voltage is 8-V greater than the input voltage. The peak voltage on BOOST is equal to the SW node voltage plus the voltage present at DBP less the bootstrap diode drop. This drop can be 1.4 V for the internal bootstrap diode or 300 mV for an external schottky diode. The voltage differential between this pin and SW is the available drive voltage for the high-side FET.
COMP 6	O	Output of the error amplifier, input to the PWM comparator. A feedback network is connected from this pin to the FB pin to compensate the overall loop. This pin is internally clamped to a 3.4-V maximum output drive capability for quicker recovery from a saturated feedback loop situation.
DBP 9	O	8-V regulator output used for the gate drive of the N-channel synchronous rectifier and as the supply for charging the bootstrap capacitor. This pin should be bypassed to ground with a 1.0- μ F ceramic capacitor.
FB 5	I	Inverting input to the error amplifier. In normal operation the voltage on this pin is equal to the internal reference voltage, 0.7 V.
GND 3	-	Ground reference for the device.
HDRV 12	O	Floating gate drive for the high-side N-channel MOSFET. This pin switches from BOOST (MOSFET on) to SW (MOSFET off).
ILIM 14	I	Short circuit protection programming pin. This pin is used to set the overcurrent threshold. An internal current sink from this pin to ground sets a voltage drop across an external resistor connected from this pin to VDD. The voltage on this pin is compared to the voltage drop ($V_{VDD} - V_{SW}$) across the high side N-channel MOSFET during conduction. Just prior to the beginning of a switching cycle this pin is pulled to approximately $V_{VDD}/2$ and released when SW is within 2 V of V_{VDD} or after a timeout (the precondition time) - whichever occurs first. Placing a capacitor across the resistor from ILIM to VDD allows the ILIM threshold to decrease during the switch on time, effectively programming the ILIM blanking time. See <i>Applications Information</i> section.
KFF 15	I	A resistor is connected from this pin to VDD programs the amount of input voltage feed-forward. The current fed into this pin is used to control the slope of the PWM ramp and program undervoltage lockout. Nominal voltage at this pin is maintained at 400 mV.
LDRV 8	O	Gate drive for the N-channel synchronous rectifier. This pin switches from DBP (MOSFET on) to PGND (MOSFET off). For proper operation, the total gate charge of the MOSFET connected to LDRV should be less than 50nC.
LVBP 17	O	4.2-V reference used for internal device logic and analog functions. This pin should be bypassed to GND with a 0.1- μ F ceramic capacitor. External loads less than 1 mA and electrically quiet may be applied.
PGD 18	O	This is an open drain output that pulls to ground when soft start is active, or when the FB pin is outside a $\pm 10\%$ band around the 700 mV reference voltage.
PGND 7		Power ground reference for the device. There should be a low-impedance path from this pin to the source(s) of the lower MOSFET(s).
RT 16	I	A resistor is connected from this pin to GND to set the switching frequency.
SA+ 20	I	Noninverting input of the remote voltage sense amplifier.
SA- 1	I	Inverting input of the remote voltage sense amplifier.
SAO 2	O	Output of the remote voltage sense amplifier.
SS 4	I	Soft-start programming pin. A capacitor connected from this pin to GND programs the soft-start time. The capacitor is charged with an internal current source of 12 μ A. The resulting voltage ramp on the SS pin is used as a second non-inverting input to the error amplifier. The voltage at this error amplifier input is approximately 1 V less than that on the SS pin. Output voltage regulation is controlled by the SS voltage ramp until the voltage on the SS pin reaches the internal offset voltage of 1 V plus the internal reference voltage of 700 mV. If SS is below the internal offset voltage of 1 V (300 mV minimum ensured), the resulting output voltage is zero. Also provides timing for fault recovery attempts. Maximum recommended capacitor is 22nF.
SW 10	I	This pin is connected to the switched node of the converter and used for overcurrent sensing as well as gate drive timing. This pin is also the return path from the high-side FET for the floating high-side FET driver. A 1.5- Ω resistor is required in series with this pin to protect against substrate current issues.
SYNC 19	I	Logic input for pulse train to synchronize oscillator.
VDD 13	I	Supply voltage for the device.

SIMPLIFIED BLOCK DIAGRAM

UDG-04076

TPS40074

SLUS617B—APRIL 2005—REVISED OCTOBER 2006

APPLICATION INFORMATION

The TPS40074 allows the user to construct synchronous voltage mode buck converters with inputs ranging from 4.5 V to 28 V and outputs as low as 700 mV. Predictive gate drive circuitry optimizes switching delays for increased efficiency and improved converter output power capability. Voltage feed-forward is employed to ease loop compensation for wide input range designs and provide better line transient response.

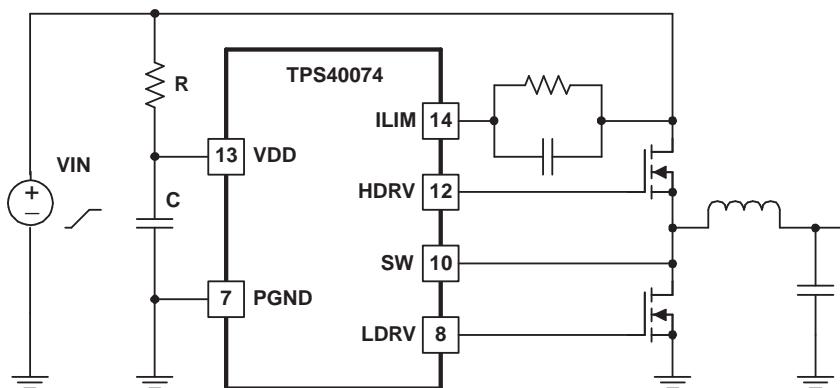

An on-board unity gain differential amplifier is provided for remote sensing in applications that require the tightest load regulation. The TPS40074 incorporates circuitry to allow startup into a pre-existing output voltage without sinking current from the source of the pre-existing output voltage. This avoids damaging sensitive loads at startup. The controller can be synchronized to an external clock source or can free run at a user programmable frequency. An integrated power good indicator is available for logic (open drain) output of the condition of the output of the converter.

MINIMUM PULSE WIDTH

The TPS40074 has limitations on the minimum pulse width that can be used to design a converter. Reliable operation is guaranteed for nominal pulse widths of 150 ns and above. This places some restrictions on the conversion ratio that can be achieved at a given switching frequency. [Figure 2](#) shows minimum output voltage for a given input voltage and frequency.

SLEW RATE LIMIT ON VDD

The regulator that supplies power for the drivers on the TPS40074 requires a limited rising slew rate on VDD for proper operation if the input voltage is above 10 V. If the slew rate is too great, this regulator can over shoot and damage to the part can occur. To ensure that the part operates properly, limit the slew rate to no more than $0.12 \text{ V}/\mu\text{s}$ as the voltage at VDD crosses 8 V. If necessary, an R-C filter can be used on the VDD pin of the device. Connect the resistor from the VDD pin to the input supply of the converter. Connect the capacitor from the VDD pin to PGND. There should not be excessive (more than a 200-mV) voltage drop across the resistor in normal operation. This places some constraints on the R-C values that can be used. [Figure 1](#) is a schematic fragment that shows the connection of the R-C slew rate limit circuit. [Equation 1](#) and [Equation 2](#) give values for R and C that limits the slew rate in the worst case condition.

UDG-05058

Figure 1. Limiting the Slew Rate

APPLICATION INFORMATION (continued)

$$R < \frac{0.2 \text{ V}}{f_{\text{SW}} \times Q_{g(\text{TOT})} + I_{\text{DD}}} \quad (1)$$

$$C > \frac{V_{\text{VIN}} - 8 \text{ V}}{R \times SR} \quad (2)$$

where

- V_{VIN} is the final value of the input voltage ramp
- f_{SW} is the switching frequency
- $Q_{g(\text{TOT})}$ is the combined total gate charge for both upper and lower MOSFETs (from MOSFET data sheet)
- I_{DD} is the TPS40074 input current (3.5 mA maximum)
- SR is the maximum allowed slew rate [12×10^4] (V/s)

SETTING THE SWITCHING FREQUENCY (PROGRAMMING THE CLOCK OSCILLATOR)

The TPS40074 has independent clock oscillator and PWM ramp generator circuits. The clock oscillator serves as the master clock to the ramp generator circuit. Connecting a single resistor from R_T to ground sets the switching frequency of the clock oscillator. The clock frequency is related to R_T by:

$$R_T = \left(\frac{1}{f_{\text{SW}}(\text{kHz}) \times 17.82 \times 10^{-6}} - 23 \right) \text{k}\Omega \quad (3)$$

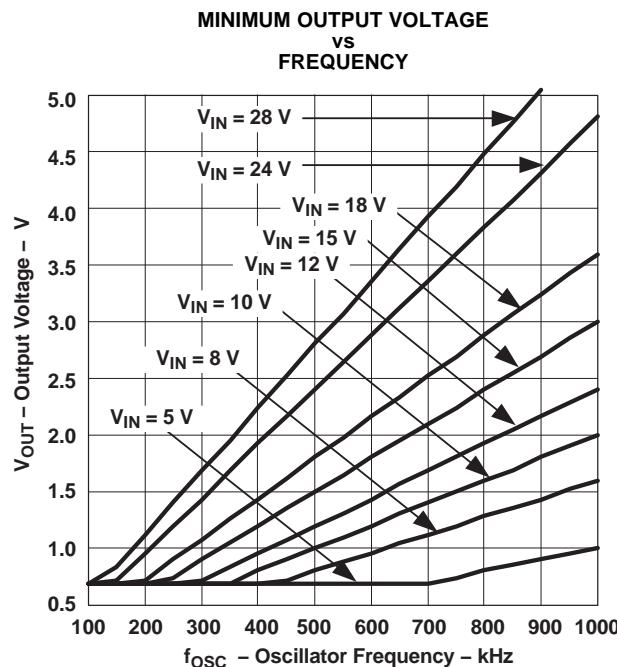

Figure 2.

TPS40074

SLUS617B-APRIL 2005-REVISED OCTOBER 2006

APPLICATION INFORMATION (continued)

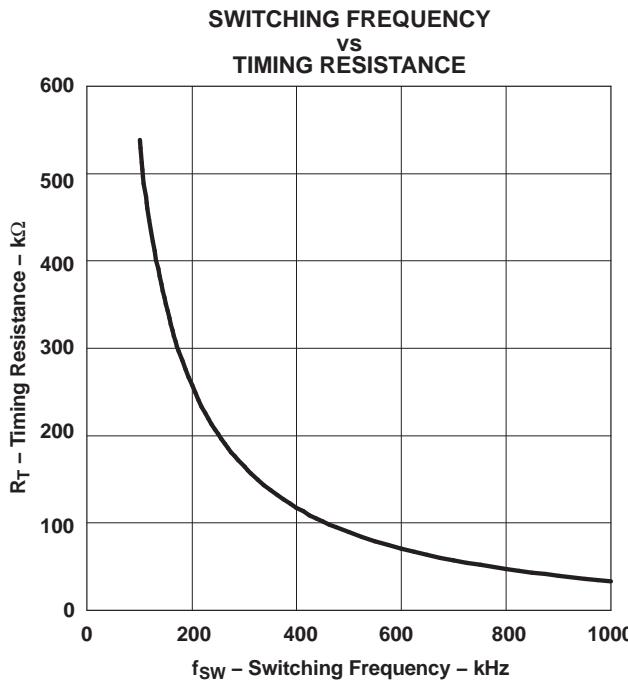

Figure 3.

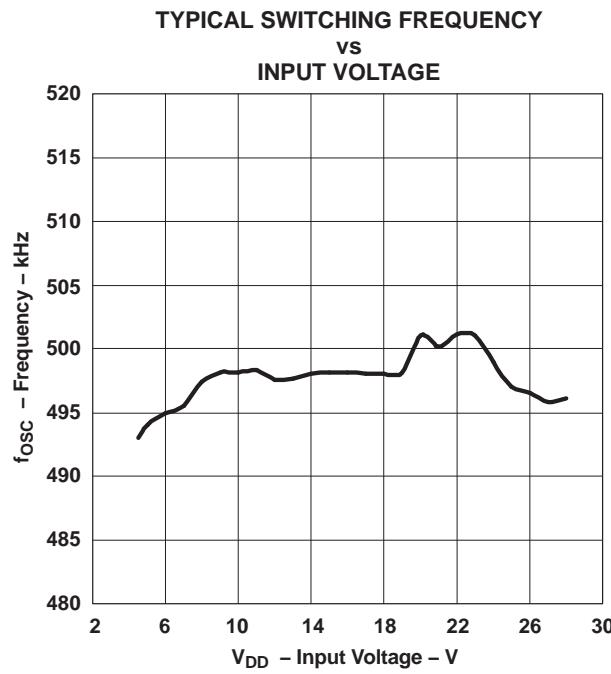

Figure 4.

PROGRAMMING THE RAMP GENERATOR CIRCUIT AND UVLO FUNCTION

The ramp generator circuit provides the actual ramp used by the PWM comparator and provides voltage feed-forward by varying the PWM ramp slope as the line voltage changes. As the input voltage to the converter increases, the slope of the PWM ramp increase by a proportionate amount. The programmable UVLO circuit works by monitoring the level reached by the PWM ramp during a clock cycle. The PWM ramp must reach approximately 1 V in amplitude during a clock cycle, or the converter is not be allowed to start. This programmable UVLO point is set via a single resistor (R_{KFF}) connected from KFF to VDD. R_{KFF} , V_{START} and R_T are related by (approximately)

$$R_{KFF} = 0.131 \times R_T \times V_{UVLO(on)} - 1.61 \times 10^{-3} \times V_{UVLO(on)}^2 + 1.886 \times V_{UVLO} - 1.363 - 0.02 \times R_T - 4.87 \times 10^{-5} \times R_T^2 \quad (4)$$

where

- $V_{UVLO(on)}$ is in volts
- R_{KFF} and R_T are in kΩ

This yields typical numbers for the programmed startup voltage. The minimum and maximum values may vary up ±15% from this number. Figure 5 through Figure 7 show the typical relationship of $V_{UVLO(on)}$, $V_{UVLO(off)}$ and R_{KFF} at three common frequencies.

APPLICATION INFORMATION (continued)

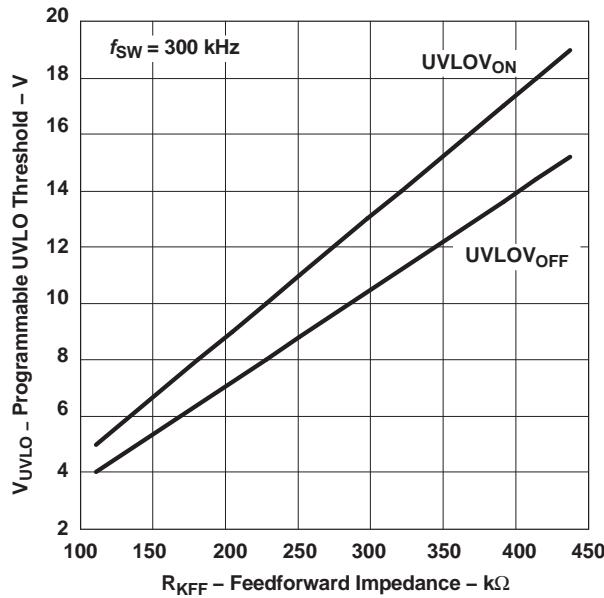

Figure 5.

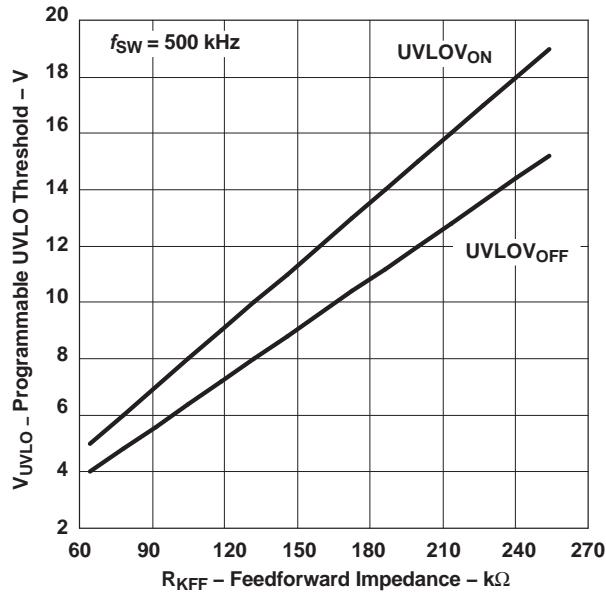

Figure 6.

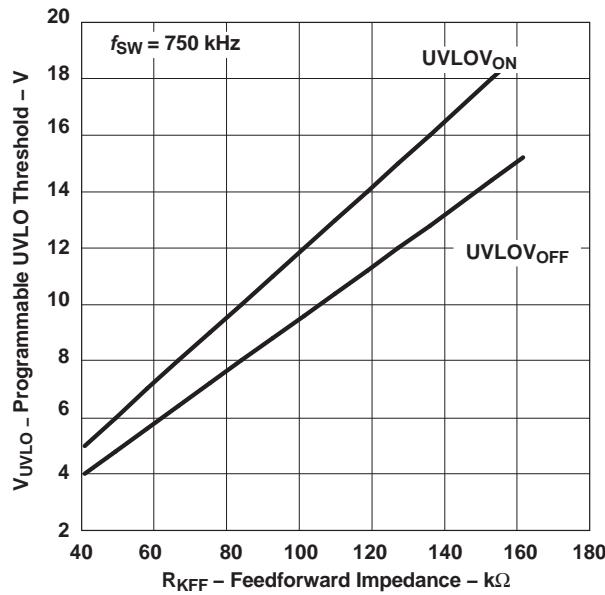

Figure 7.

TPS40074

SLUS617B—APRIL 2005—REVISED OCTOBER 2006

APPLICATION INFORMATION (continued)

The programmable UVLO circuit incorporates 20% hysteresis from the start voltage to the shutdown voltage. For example, if the startup voltage is programmed to be 10 V, the controller starts when V_{DD} reaches 10 V and shuts down when V_{DD} falls below 8 V. The maximum duty cycle begins to decrease as the input voltage rises to twice the startup voltage. Below this point, the maximum duty cycle is as specified in the electrical table. Note that with this scheme, the theoretical maximum output voltage that the converter can produce is approximately two times the programmed startup voltage. For design, set the programmed startup voltage equal to or greater than the desired output voltage divided by maximum duty cycle (85% for frequencies 500 kHz and below). For example, a 5-V output converter should not have a programmed startup voltage below 5.9 V. [Figure 8](#) shows the theoretical maximum duty cycle (typical) for various programmed startup voltages

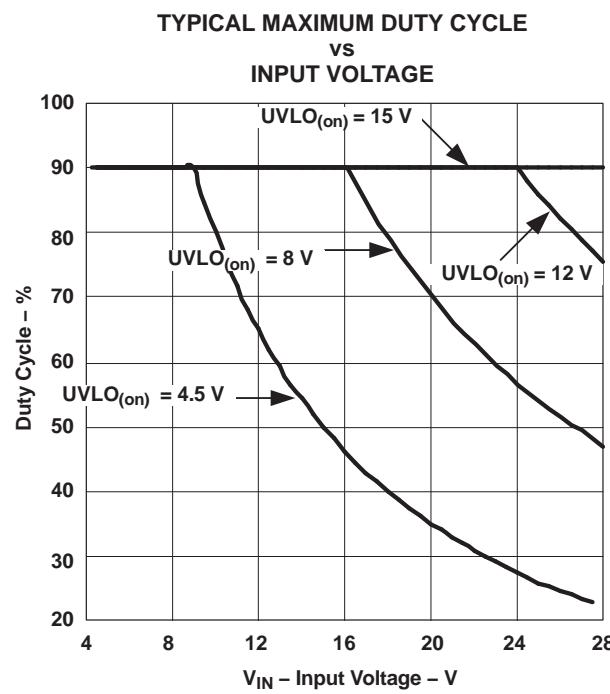

Figure 8.

APPLICATION INFORMATION (continued)

Figure 9 shows the effect of changing input voltage on the duty cycle, and how that change takes place. The pulse width modulator (PWM) ramp input is generated using a current that is proportional to the current into the KFF pin. The TPS40074 holds this pin at a constant 400 mV, so connecting a resistor from KFF to the input power supply causes a current to flow into the KFF pin that is proportional to the input voltage. The slope of the ramp signal to the PWM is therefore proportional to the input voltage. This allows the duty cycle to change with variations in V_{IN} without requiring much response from the error amplifier, resulting in very good line transient response. Another benefit is essentially constant PWM gain over the entire input voltage operating range. This makes the output control loop easier to design for a wide input range converter.

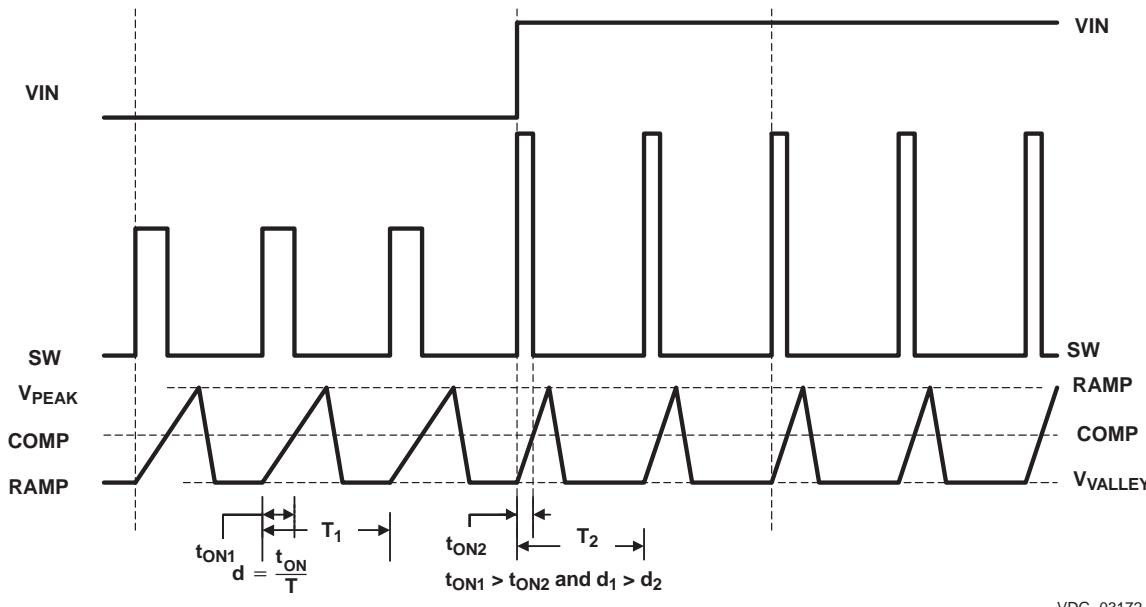

Figure 9. Voltage Feed-Forward and PWM Duty Cycle Waveforms

PROGRAMMING SOFT START

TPS40074 uses a closed-loop approach to ensure a controlled ramp on the output during start-up. Soft-start is programmed by connecting an external capacitor (C_{SS}) from the SS pin to GND. This capacitor is charged by a fixed current, generating a ramp signal. The voltage on SS is level shifted down approximately 1 V and fed into a separate non-inverting input to the error amplifier. The loop is closed on the lower of the level shifted SS voltage or the 700-mV internal reference voltage. Once the level shifted SS voltage rises above the internal reference voltage, output voltage regulation is based on the internal reference. To ensure a controlled ramp-up of the output voltage the soft-start time should be greater than the $L-C_{OUT}$ time constant or:

$$t_{START} \geq 2\pi \times \sqrt{L \times C_{OUT}} \quad (\text{seconds}) \quad (5)$$

where

- L is the value of the filter inductor
- C_{OUT} is the value of the output capacitance
- t_{START} is the output ramp up-time

For a desired soft-start time, the soft-start capacitance, C_{SS} , can be found from:

$$C_{SS} \times t_{SS} = \frac{I_{SS}}{V_{FB}} \quad (6)$$

To ensure correct start up of the converter, the soft-start time is limited and can be calculated using Equation 7.

TPS40074

SLUS617B-APRIL 2005-REVISED OCTOBER 2006

APPLICATION INFORMATION (continued)

$$t_{\text{START}} \leq \frac{D_{\text{MIN}}}{f_{\text{SW}} \times 10^{-7}} \text{ ms} \quad (7)$$

where

- D_{MIN} is the minimum operating duty cycle
- f_{SW} is the converter switching frequency

Please note: There is a direct correlation between t_{START} and the input current required during start-up. The lower t_{START} is, the higher the input current required during start-up since the output capacitance must be charged faster.

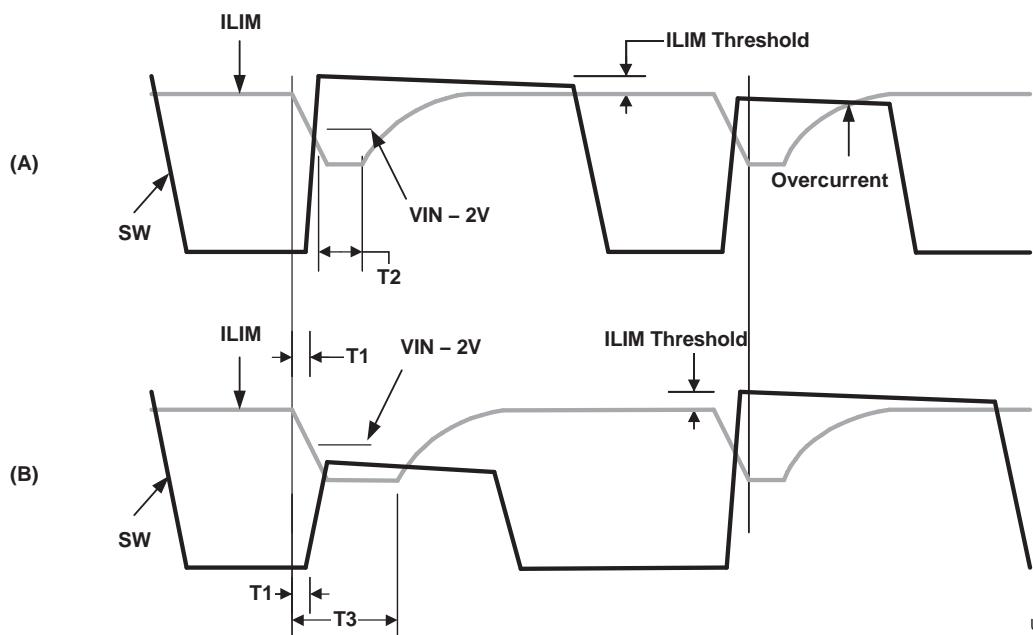

PROGRAMMING SHORT CIRCUIT PROTECTION

The TPS40074 uses a two-tier approach to short circuit protection. The first tier is a pulse-by-pulse protection scheme. Short circuit protection is implemented by sensing the voltage drop across the high-side MOSFET while it is turned on. The MOSFET drain to source voltage is compared to the voltage dropped across a resistor (R_{ILIM}) connected from VDD to the ILIM pin. The voltage drop across this resistor is produced by a constant current sink. If the voltage drop across the MOSFET exceeds the voltage drop across the ILIM resistor the switching pulse is immediately terminated. The MOSFET remains off until the next switching cycle is initiated.

In addition, just prior to the high-side MOSFET turning on, the ILIM pin is pulled down to approximately half of VDD. The ILIM pin is allowed to return to its nominal value after one of two events occur:

1. The SW node rises to within approximately 2 V of VDD
2. An internal timeout occurs, approximately 125-ns after ILIM is initially pulled down

If the SW node rises to within approximately 2-V of VDD, the device allows ILIM to go back to its nominal value. This is illustrated in Figure 10 A. T1 is the delay time from the internal PWM signal being asserted and the rise of SW. This includes the driver delay of 50 ns typical, and the turn on time of the high-side MOSFET. The MOSFET used should have a turn on time less than 75 ns. T2 is the reaction time of the sensing circuit that allows ILIM to start to return to its nominal value, typically 20ns.

UDG-03173

Figure 10. Switching and Current Limit Waveforms and Timing Relationship

APPLICATION INFORMATION (continued)

The second event that can cause ILIM to return to its nominal value is for an internal timeout to expire. This is illustrated in [Figure 10](#) B as T3. Here SW never rises to VDD-2, for whatever reason, and the internal timer times out. This allows the ILIM pin to start its transition back to its nominal value.

Prior to ILIM starting back to its nominal value, short circuit sensing is not enabled. In normal operation, this insures that the SW node is at a higher voltage than ILIM when short circuit sensing starts, avoiding false trips while allowing for a quicker blanking delay than would ordinarily be possible. Placing a capacitor across R_{ILIM} sets an exponential approach to the normal voltage at the ILIM pin. This exponential “decay” of the short circuit threshold can be used to compensate for ringing on the SW node after its rising edge and to help compensate for slower turn-on MOSFETs. Choosing the proper capacitance requires care. If the capacitance is too large, the voltage at ILIM does not approach the desired short circuit level quickly enough, resulting in an apparent shift in short circuit threshold as pulse width changes.

The comparator that looks at ILIM and SW to determine if a short circuit condition exists has a clamp on its SW input. This clamp makes the SW node never appear to fall more than 1.4 V (approximately, could be as much as 2 V at -40°C) below VDD. While ILIM is more than 1.4 V below VDD short circuit sensing is effectively disabled, giving a programmable absolute blanking time. As a general rule, it is best to make the time constant of the R-C at the ILIM pin 20% or less of the nominal pulse width of the converter (See [Equation 13](#))

The second tier protection incorporates a fault counter. The fault counter is incremented on each cycle with an overcurrent pulse and decremented on a clock cycle without an overcurrent pulse. When the counter reaches seven (7) a fault condition is declared by the controller. When this happens, the output drivers turn both MOSFETs off. Seven soft-start cycles are initiated (without activity on the HDRV and LDRV outputs) and the PWM is disabled during this period. The counter is decremented on each soft-start cycle. When the counter is decremented to zero the PWM is re-enabled and the controller attempts to restart. If the fault has been removed the output starts up normally. If the output fault is still present the counter counts seven overcurrent pulses and re-enters the second tier fault mode. Refer to [Figure 11](#) for typical fault protection waveforms.

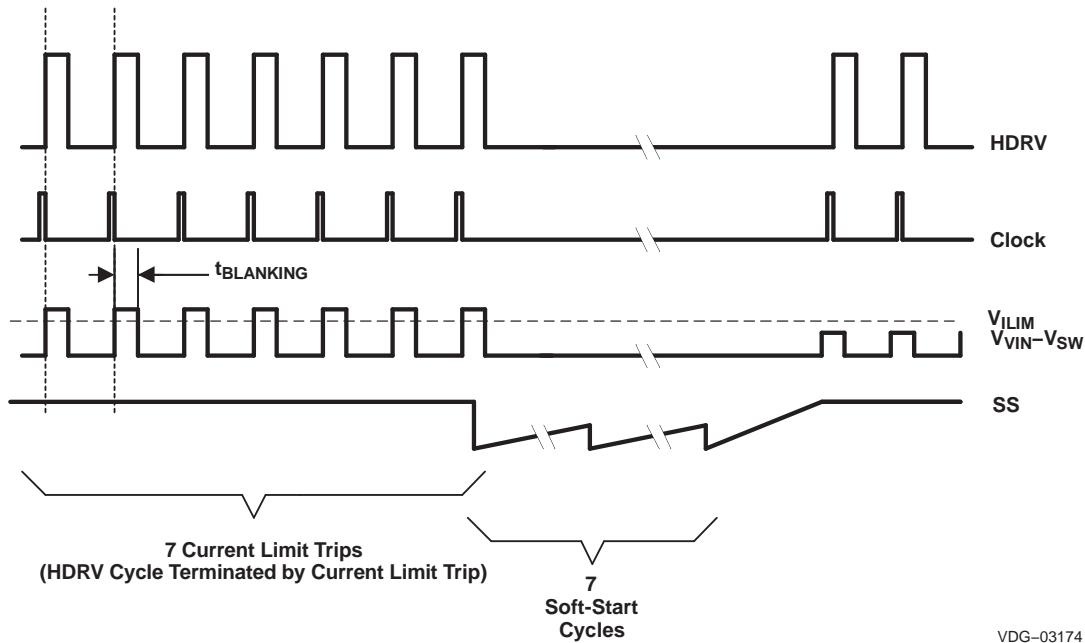

Figure 11. Typical Fault Protection Waveforms

TPS40074

SLUS617B-APRIL 2005-REVISED OCTOBER 2006

APPLICATION INFORMATION (continued)

The minimum short circuit limit threshold (I_{SCP}) depends on t_{START} , C_{OUT} , V_{OUT} , and the load current at turn-on (I_{LOAD}).

$$I_{SCP} > \frac{C_{OUT} \times V_{OUT}}{t_{START}} + I_{LOAD} \quad (A) \quad (8)$$

The short circuit limit programming resistor (R_{ILIM}) is calculated from:

$$R_{ILIM} = \frac{100 \times (R_{DS(on)MAX} \times I_{SCP} + V_{ILIM(ofst)}) + 9 \times R_{VDD} \times I_{RVDD} + 4.5 \text{ V}}{109 \times I_{ILIM}} \Omega \quad (9)$$

where

- I_{ILIM} is the current into the ILIM pin (135 μA typical)
- $V_{ILIM(ofst)}$ is the offset voltage of the ILIM comparator (-30 mV typical)
- I_{SCP} is the short-circuit protection current
- $R_{DS(on)MAX}$ is the drain-to-source resistance of the high-side MOSFET
- R_{VDD} is the slew rate limit resistor if used
- I_{RVDD} is the current through R_{VDD} and can be calculated using [Equation 10](#).

$$I_{RVDD} = f_{SW} \times Q_g + I_{DD} \quad (10)$$

where

- f_{SW} is the switching frequency
- $Q_{g(TOT)}$ is the combined total gate charge from both upper and lower MOSFETs (from MOSFET datasheet)
- I_{DD} is the TPS40074 input current (3.5-mA maximum)

To find the range of the short circuit threshold values use the following equations.

$$I_{SCP(max)} = \frac{1.09 \times I_{ILIM(max)} \times R_{ILIM} - 0.09 \times R_{VDD} \times I_{RVDD} - 0.045 + 50 \text{ mV}}{R_{DS(on)MIN}} \text{ A} \quad (11)$$

$$I_{SCP(min)} = \frac{1.09 \times I_{ILIM(min)} \times R_{ILIM} - 0.09 \times R_{VDD} \times I_{RVDD} - 0.045 + 10 \text{ mV}}{R_{DS(on)MAX}} \text{ A} \quad (12)$$

The TPS40074 provides short-circuit protection only. As such, it is recommended that the minimum short circuit protection level be placed at least 20% above the maximum output current required from the converter. The maximum output of the converter should be the steady state maximum output plus any transient specification that may exist.

The ILIM capacitor maximum value can be found from:

$$C_{ILIM(max)} = \frac{V_{OUT} \times 0.2}{V_{IN} \times R_{ILIM} \times f_{SW}} \text{ (Farads)} \quad (13)$$

Note that this is a recommended maximum value. If a smaller value can be used, it should be to improve protection. For most applications, consider using half the maximum value shown in [Equation 13](#).

BOOST AND DBP BYPASS CAPACITANCE

The BOOST capacitance provides a local, low-impedance flying source for the high-side driver. The BOOST capacitor should be a good quality, high-frequency ceramic capacitor. A minimum value of 100-nF is suggested.

The DBP capacitor has to provide energy storage for switching both the synchronous MOSFET and the high-side MOSFET (via the BOOST capacitor). The suggested value for this capacitor is 1- μF ceramic, minimum.

APPLICATION INFORMATION (continued)

INTERNAL REGULATORS

The internal regulators are linear regulators that provide controlled voltages for the drivers and the internal circuitry to operate from. The low-side driver operates directly from the 8-V regulator supply while the high-side driver bootstrap capacitor is charged from this supply. The actual voltage delivered to the high-side driver is the voltage on the DBP pin less any drop from the bootstrap diode. If the internal bootstrap diode is used, the drop across that diode is nominally 1.4 V at room temperature. This regulator has two modes of operation. At voltages below 8.5 V on VDD, the regulator is in a low dropout mode of operation and tries to provide as little impedance as possible from VDD to DBP. When VDD is above 10 V, the regulator regulates DBP to 8 V. Between these two voltages, the regulator is in whatever state it was in when VDD entered this region. The LVBP pin is connected to a 4.2-V regulator that supplies power for the internal control circuitry. Small amounts of current can be drawn from these pins for other external circuit functions, as long as power dissipation in the controller chip remains at acceptable levels and junction temperature does not exceed 125°C. Any external load connected to LVBP should be electrically quiet to avoid degrading performance of the TPS40074. Typical output voltages for these two regulators are shown in [Figure 12](#) and [Figure 13](#).

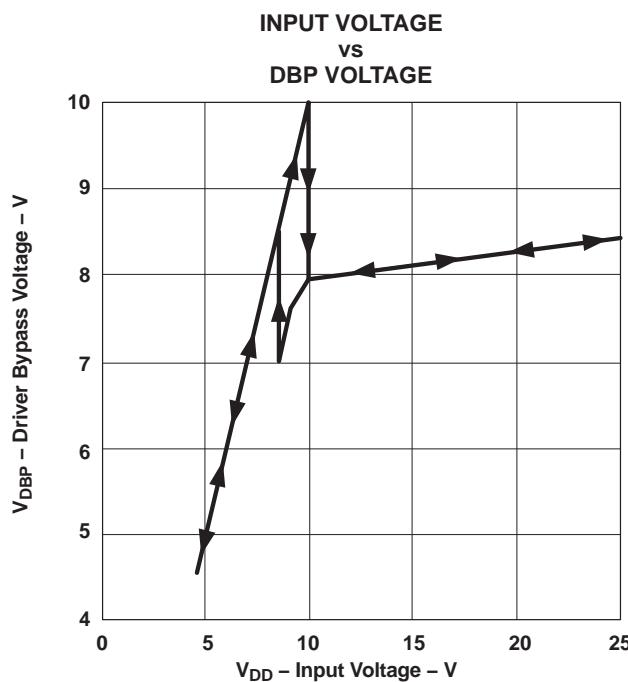

Figure 12.

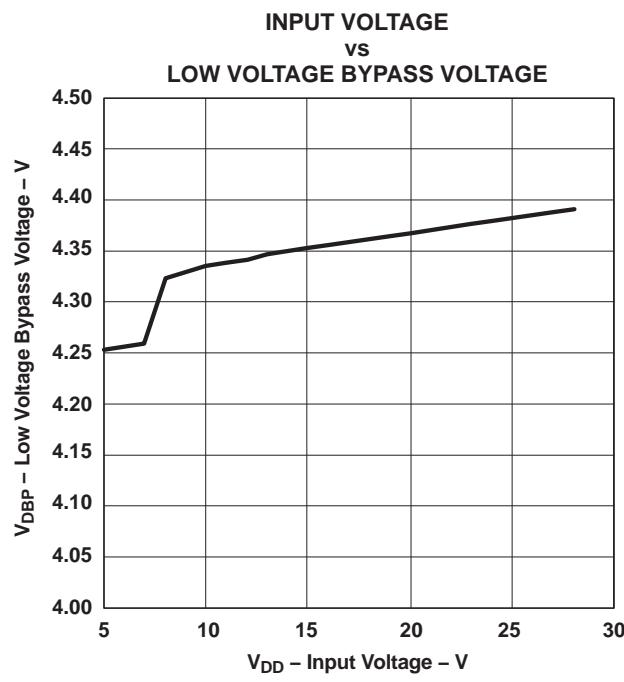

Figure 13.

DIFFERENTIAL SENSE AMPLIFIER

The TPS40074 has an on board differential amplifier intended for use as a remote sensing amplifier for the output voltage. Use of this amplifier for remote sensing eliminates load regulation issues due to voltage drops that occur between the converter and the actual point of load. The amplifier is powered from the DBP pin and can be used to monitor output voltages up to 6 V with a DBP voltage of 8 V. For lower DBP voltages, the sense amplifier can be used to monitor output voltages up to 2-V below the DBP voltage. The internal resistors used to configure the amplifier for unity gain match each other closely, but their absolute values can vary as much as 30%, so adding external resistance to alter the gain is not accurate in a production environment.

TPS40074

SLUS617B-APRIL 2005-REVISED OCTOBER 2006

APPLICATION INFORMATION (continued)**SYNCHRONIZATION**

The SYNC pin accepts logic level signals and is used to synchronize the TPS40074 to an external clock source. Synchronization occurs on the rising edge of the signal at the SYNC pin. There is a fixed delay of approximately 300 ns from the rising edge of the waveform at SYNC to the HDRV output turning on the high-side FET. The pin may be left floating in this function is not used, or it may be connected to GND. The frequency of the external clock must be greater than the free running frequency of the device as set by the resistor on the RT pin (R_{RT}). This pin requires a totem pole drive, or open collector/drain if pull up resistor to either LVBP or a separate supply between 2.5 V and 5 V is used. Synchronization does not affect the modulator gain due to the voltage feed forward circuitry. The programmable UVLO thresholds are affected by synchronization. The thresholds are shifted by the ratio of the sync frequency to the free running frequency of the converter. For example, synchronizing to a frequency 20% higher than the free running frequency results in the programmable UVLO thresholds shifting up 20% from their calculated free run values. The synchronization frequency should be kept less than 1.5 times the free run frequency for best performance, although higher multiples can be used.

POWERGOOD OPERATION

The PGD pin is an open drain output that actively pulls to GND if any of the following conditions are met (assuming that the input voltage is above 4.5 V)

- Soft-start is active ($V_{VSS} < 3.5$ V)
- $V_{FB} < 0.63$ V
- $V_{FB} > 0.77$ V
- Programmable UVLO condition not satisfied (V_{IN} below programmed level)
- Overcurrent condition exists
- Die temperature is greater than 165°C

PRE-BIASED OUTPUTS

Some applications require that the converter not sink current during startup if a pre-existing voltage exists at the output. Since synchronous buck converters inherently sink current some method of overcoming this characteristic must be employed. Applications that require this operation are typically power rails for a multi supply processor or ASIC. The method used in this controller, is to not allow the low side or rectifier FET to turn on until there the output voltage commanded by the start up ramp is higher than the pre-existing output voltage. This is detected by monitoring the internal pulse width modulator (PWM) for its first output pulse. Since this controller uses a closed loop startup, the first output pulse from the PWM does not occur until the output voltage is commanded to be higher than the pre-existing voltage. This effectively limits the controller to sourcing current only during the startup sequence.

If the pre-existing voltage is higher than the intended regulation point for the output of the converter, the converter starts and sinks current when the soft-start time has completed

OUTPUT RIPPLE CONSIDERATION

In addition to the typical output ripple associated with switching converters, (which can vary from 5 mV to 150 mV) the TPS40074 exhibits a low-frequency ripple from 5 mV to 50 mV. The ripple, a consequence of the charge pump in the driver supply regulator, is well bounded under changes in line, load, and temperature. The ripple frequency does vary with the converter switching frequency and can vary from 10 kHz to 60 kHz.

APPLICATION INFORMATION (continued)

TPS40074 POWER DISSIPATION

The power dissipation in the TPS40074 is largely dependent on the MOSFET driver currents and the input voltage. The driver current is proportional to the total gate charge, Q_g , of the external MOSFETs. Driver power (neglecting external gate resistance) can be calculated from:

$$P_D = Q_g \times V_{DR} \times f_{SW} \quad (\text{Watts/driver}) \quad (14)$$

where

- V_{DR} is the driver output voltage

The total power dissipation in the TPS40074, assuming the same MOSFET is selected for both the high-side and synchronous rectifier is described in [Equation 15](#).

$$P_T = \left(\frac{2 \times P_D}{V_{DR}} + I_Q \right) \times V_{IN} \quad (\text{Watts}) \quad (15)$$

or

$$P_T = (2 \times Q_g \times f_{SW} + I_Q) \times V_{IN} \quad (\text{Watts}) \quad (16)$$

where

- I_Q is the quiescent operating current (neglecting drivers)

The maximum power capability of the TPS40074 PowerPAD package is dependent on the layout as well as air flow. The thermal impedance from junction to air ambient assuming 2-oz. copper trace and thermal pad with solder and no air flow is $\theta_{JA} = 60 \text{ }^{\circ}\text{C/W}$

The maximum allowable package power dissipation is related to ambient temperature by [Equation 17](#).

$$P_T = \frac{T_J - T_A}{\theta_{JA}} \quad (\text{Watts}) \quad (17)$$

Substituting [Equation 17](#) into [Equation 16](#) and solving for f_{SW} yields the maximum operating frequency for the TPS4007x. The result is described in [Equation 18](#).

$$f_{SW} = \frac{\left(\left[\frac{(T_J - T_A)}{(\theta_{JA} \times V_{IN})} \right] - I_Q \right)}{(2 \times Q_g)} \quad (\text{Hz}) \quad (18)$$

BOOST DIODE

The TPS40074 has internal diodes to charge the boost capacitor connected from SW to BOOST. The drop across this diode is rather large at 1.4-V nominal at room temperature resulting in the drive voltage to the high-side MOSFET being reduced by this amount from the DBP voltage. If this drop is too large for a particular application, an external diode may be connected from DBP (anode) to BOOST (cathode). This provides significantly improved gate drive for the high-side MOSFET, especially at lower input voltages.

LOW VOLTAGE OPERATION

If the programmable UVLO is set to less than 6.5 V nominal, connect a 330-k Ω resistor across the soft-start capacitor. This eliminates a race condition inside the device that can lead to an output voltage overshoot on power down of the part.

TPS40074

SLUS617B-APRIL 2005-REVISED OCTOBER 2006

APPLICATION INFORMATION (continued)

GROUNDING AND BOARD LAYOUT

The TPS40074 provides separate signal ground (GND) and power ground (PGND) pins. Care should be given to proper separation of the circuit grounds. Each ground should consist of a plane to minimize its impedance if possible. The high power *noisy* circuits such as the output, synchronous rectifier, MOSFET driver decoupling capacitor (DBP), and the input capacitor should be connected to PGND plane.

Sensitive nodes such as the FB resistor divider and RT should be connected to the GND plane. The GND plane should only make a single point connection to the PGND plane. It is suggested that the GND pin be tied to the copper area for the PowerPAD underneath the chip. Tie the PGND to the PowerPAD copper area as well and make the connection to the power circuit ground from the PGND pin. Reference the output voltage divider to the GND pin.

Component placement should ensure that bypass capacitors (LVPB and DBP) are located as close as possible to their respective power and ground pins. Also, sensitive circuits such as FB, RT and ILIM should not be located near high dv/dt nodes such as HDRV, LDRV, BOOST, and the switch node (SW). Failure to follow careful layout practices results in sub-optimal operation.

SYNCHRONOUS RECTIFIER CONTROL

Table 2 describes the state of the rectifier MOSFET control under various operating conditions.

Table 2. Synchronous Rectifier MOSFET States

SYNCHRONOUS RECTIFIER OPERATION DURING			
SOFT-START	NORMAL	FAULT (FAULT RECOVERY IS SAME AS SOFT-START)	OVERVOLTAGE
Off until first high-side pulse is detected, then on when high-side MOSFET is off	Turns off at the start of a new cycle. Turns on when the high-side MOSFET is turned off	OFF	Turns OFF only at start of next cycle ON if duty cycle is > 0

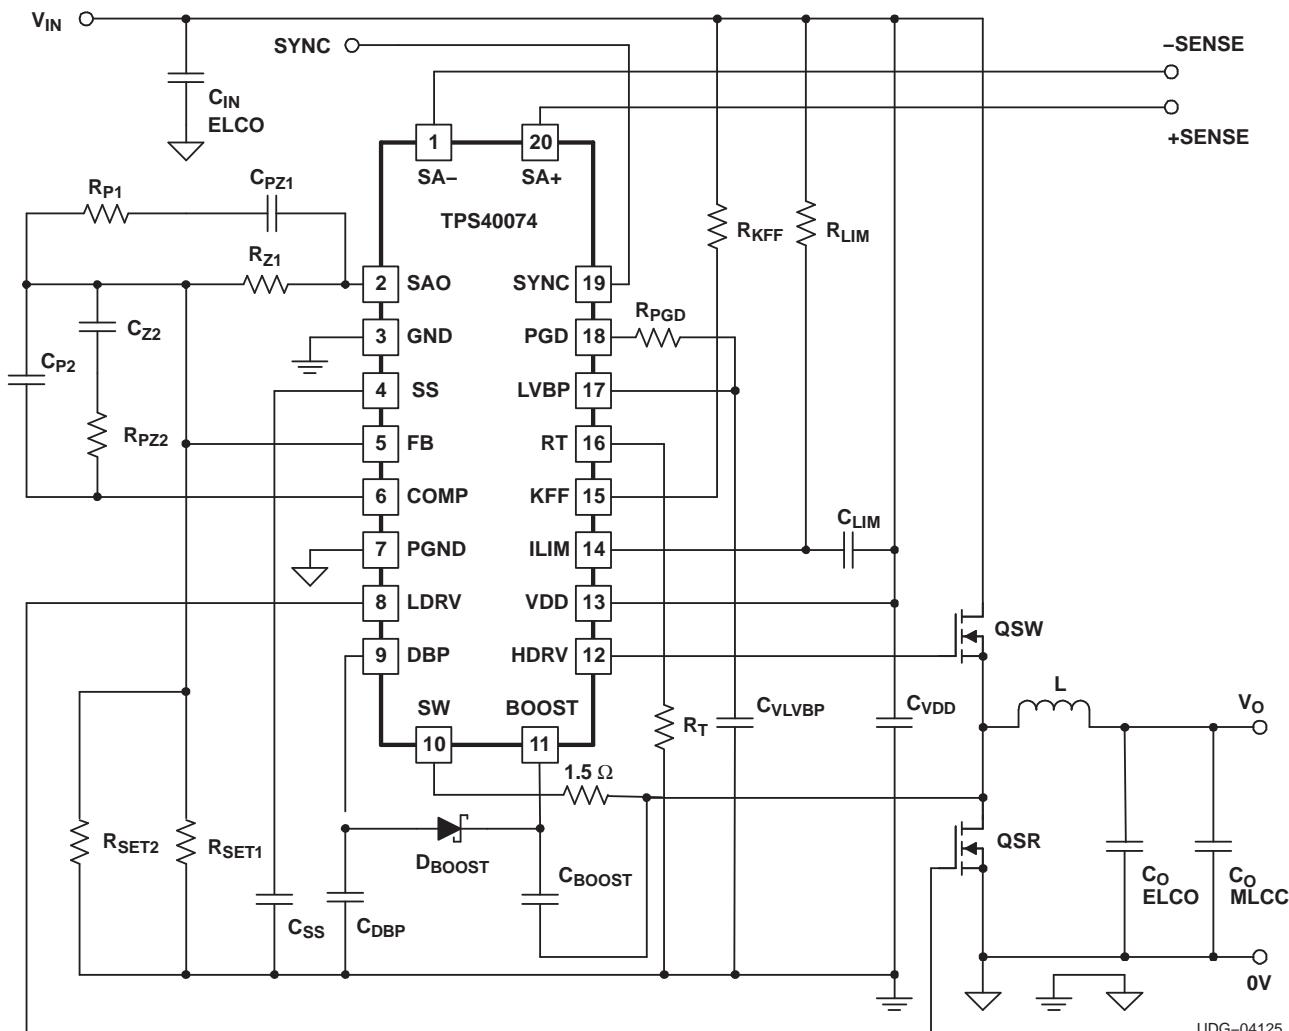

For proper operation, the total gate charge of the MOSFET connected to LDRV should be less than 50nC.

DESIGN EXAMPLE

1. SPECIFICATIONS

PARAMETER		TEST CONDITIONS	MIN	TYP	MAX	UNIT
INPUT CURRENT						
V _{IN}	Input voltage		10.8	12.0	13.2	V
V _O	Output voltage	I _{OUT} = 10 A		1.5	5	
	Regulation		1.47		1.53	
V _{RIPPLE}	Output ripple voltage	I _{O(max)} = 15 A		30		mV
V _{OVER}	Output overshoot	I _{STEP} = 8 A		50		
V _{UNDER}	Output undershoot	I _{STEP} = 8 A		50		
I _{LOAD}	Output current		0		15	A
I _{SCP}	Short circuit current trip point		16		30	
η	Efficiency	V _{IN} = 12 V, I _{LOAD} = 15 A		85%		
f _{SW}	Switching frequency		400			kHz

TPS40074

SLUS617B-APRIL 2005-REVISED OCTOBER 2006

3. COMPONENT SELECTION

3.1 Power Train Components

Designers familiar with the buck converter can skip to section **3.2 Component Selection for TPS40074**.

3.1.1 Output Inductor, L_O

The output inductor is one of the most important components to select. It stores the energy necessary to keep the output regulated when the switch MOSFET is turned off. The value of the output inductor dictates the peak and RMS currents in the converter. These currents are important when selecting other components. [Equation 19](#) can be used to calculate a value for L .

$$L = \frac{V_O}{V_{IN(max)}} \times \frac{(V_{IN(max)} - V_O)}{f_{SW} \times \Delta I} \quad (19)$$

ΔI is the allowable ripple in the inductor. Selecting ΔI also sets the output current when the converter goes into discontinuous mode (DCM) operation. Since this converter utilizes MOSFETs for the rectifier, DCM is not a major concern. Select ΔI to be between 20% and 30% of maximum I_{LOAD} . For this design, ΔI of 3 A was selected. The calculated L is 1.1 μ H. A standard inductor with value of 1.0 μ H was chosen. This increases ΔI by about 10% to 3.3 A.

With this ΔI value, calculate the RMS and peak current flowing in L_O . Note this peak current is also seen by the switching MOSFET and synchronous rectifier.

$$I_{LOAD_RMS} = \sqrt{I_{LOAD}^2 + \frac{\Delta I^2}{12}} = 15.03 \text{ A} \quad (20)$$

$$I_{PK} = I_{LOAD} + \frac{\Delta I^2}{2} = 16.65 \text{ A} \quad (21)$$

3.1.2 Output Capacitor, C_O , ELCO and MLCC

Several parameters must be considered when selecting the output capacitor. The capacitance value should be selected based on the output overshoot, V_{OVER} , and undershoot, V_{UNDER} , during a transient load, I_{STEP} , on the converter. The equivalent series resistance (ESR) is chosen to allow the converter meet the output ripple specification, V_{RIPPLE} . The voltage rating must be greater than the maximum output voltage. Other parameters to consider are: equivalent series inductance which is important in fast transient load situations. Also size and technology can be factors when choosing the output capacitor. In this design a large capacitance electrolytic type capacitor, C_O ELCO, is used to meet the overshoot and under shoot specifications. Its ESR is chosen to meet the output ripple specification. While a smaller multiple layer ceramic capacitor, C_O MLCC, is used to filter high frequency noise.

The minimum required capacitance and maximum ESR can be calculated using the equations below.

$$C_O > \frac{L \times I_{STEP}^2}{2 \times V_{UNDER} \times D_{MAX} \times (V_{IN} - V_O)} \quad (22)$$

$$C_O > \frac{L \times I_{STEP}^2}{2 \times V_{OVER} \times V_O} \quad (23)$$

$$ESR < \frac{V_{RIPPLE}}{\Delta I} \quad (24)$$

Using [Equation 22](#) through [Equation 24](#), the capacitance for C_O should be greater than 495 μ F and its ESR should be less than 9.1 $\text{m}\Omega$. The 1000 μ F/25 V capacitor from Rubycon's MBZ or Panasonic's series EEU-FL was chosen. Its ESR is 19 $\text{m}\Omega$, so two in parallel are used. The slightly higher ESR is offset by the four times increase in capacitance. A 2.2 μ F/16 V MLCC is also added in parallel to reduce high frequency noise.

3.1.3. Input Capacitor, C_{IN} , ELCO and MLCC

The input capacitor is selected to handle the ripple current of the buck stage. Also a relative large capacitance is used to keep the ripple voltage on the supply line low. This is especially important where the supply line is high impedance. It is recommended that the supply line be kept low impedance. The input capacitor ripple current can be calculated using [Equation 25](#).

$$I_{CAP(RMS)} = \sqrt{\left[\left(I_{LOAD(max)} - I_{IN(avg)}^2 \right) + \frac{\Delta I^2}{12} \right] \times D + I_{IN(avg)}^2 \times (1 - D)} \quad (25)$$

where

- $I_{IN(avg)}$ is the average input current

This is calculated simply by multiplying the output DC current by the duty cycle. The ripple current in the input capacitor is 5.05 A. A 1206 MLCC using X7R material has a typical dissipation factor of 5%. For a 2.2 μ F capacitor at 400 kHz the ESR is approximately 7.2 m Ω . If two capacitors are used in parallel the power dissipation in each capacitor is less than 46 mW.

A 470 μ F/16 V electrolytic capacitor is added to maintain the voltage on the input rail.

3.1.4 Switching MOSFET, QSW

The following key parameters must be met by the selected MOSFET.

- Drain source voltage, V_{DS} , must be able to withstand the input voltage plus spikes that may be on the switching node. For this design a V_{DS} rating of 25 V to 30 V is recommended.
- Drain current, I_D , at 25°C, must be greater than that calculated using [Equation 26](#). For this design, I_D should be greater than 5 A.

$$I_D = \sqrt{\frac{V_O}{V_{IN(min)}} \times \left(I_{LOAD(max)}^2 + \frac{\Delta I^2}{12} \right)} \quad (26)$$

- Gate source voltage, V_{GS} must be able to withstand the gate voltage from the control device . For the TPS40074 this is 9 V.

Once the above boundary parameters are defined the next step in selecting the switching MOSFET is to select the key performance parameters. Efficiency is the performance characteristic which drives the other selection criteria. Target efficiency for this design is 90%. Based on 1.5-V output and 15 A this equates to a power loss in the converter of 2.5 W. Using this figure a target of 0.5 W dissipated in the switching MOSFET was chosen.

TPS40074

SLUS617B-APRIL 2005-REVISED OCTOBER 2006

Equation 27 through Equation 30 can be used to calculate the power loss, P_{QSW} , in the switching MOSFET

$$P_{QSW} = P_{QSW(ON)} + P_{QSW(SW)} + P_{QSW(GATE)} \quad (27)$$

$$P_{QSW(ON)} = R_{DS(on)} \times I_D^2 = R_{DS(on)} \times \frac{V_O}{V_{IN}} \times \left(I_{LOAD}^2 + \frac{\Delta I^2}{12} \right) \quad (28)$$

$$P_{QSW(SW)} = V_{IN} \times f_{SW} \times \left[\frac{\left(I_{LOAD} + \frac{\Delta I}{2} \right) \times (Q_{gs1} + Q_{gd})}{I_g} + \frac{Q_{OSS(SW)} + Q_{OSS(SR)}}{2} \right] \quad (29)$$

$$P_{QSW(GATE)} = Q_{g(TOT)} \times V_g \times F_{SW} \quad (30)$$

where

- $P_{QSW(ON)}$ = conduction losses
- $P_{QSW(SW)}$ = switching losses
- $P_{QSW(GATE)}$ = gate drive losses
- Q_{gd} = drain source charge or miller charge
- Q_{gs1} = gate source post threshold charge
- I_g = gate drive current
- $Q_{OSS(SW)}$ = switching MOSFET output charge
- $Q_{OSS(SR)}$ = synchronous MOSFET output charge
- $Q_{g(TOT)}$ = total gate charge from zero volts to the gate voltage
- V_g = gate voltage

If the total estimated loss is split evenly between conduction and switching losses, Equation 27 and Equation 28 yields preliminary values for $R_{DS(on)}$ and $(Q_{gs1} + Q_{gd})$. Note output losses due to Q_{OSS} and gate losses have been ignored here. Once a MOSFET is selected these parameters can be added.

The switching MOSFET for this design should have an $R_{DS(on)}$ of less than 9 mΩ. The sum of Q_{gd} and Q_{gs} should be approximately 4 nC.

It is not always possible to get a MOSFET which meets both these criteria so a comprise may have to be made. Also by selecting different MOSFETs close to this criteria and calculating power loss the final selection can be made. It was found that the PH6325L MOSFET from Philips semiconductor gave reasonable results. This device has an $R_{DS(on)}$ of 6.3 mΩ and a $(Q_{gs1}+Q_{gd})$ of 5.9 nC. The estimated conduction losses are 0.178 W and the switching losses are 0.270 W. This gives a total estimated power loss of 0.448 W versus 0.5 W for our initial boundary condition. Note this does not include gate losses of approximately 10 mW and output losses of less than 1 mW.

3.1.5 Rectifier MOSFET, QSR

Similar criteria can be used for the rectifier MOSFET. There is one significant difference. Due to the body diode conducting, the rectifier MOSFET switches with near zero voltage across its drain and source so effectively with near zero switching losses. However, there are some losses in the body diode. These are minimized by reducing the delay time between the transition from the switching MOSFET turn off to rectifier MOSFET turn on and vice versa. The TPS40074 incorporates TI's proprietary predictive gate drive which helps reduce this delay to between 10 ns and 20 ns.

The calculations for the losses in the rectifier MOSFET are show in [Equation 31](#) through [Equation 34](#).

$$P_{QSR} = P_{QSR(CON)} + P_{DIODE} + P_{QSR(GATE)} \quad (31)$$

$$P_{QSR(CON)} = R_{DS(on)} \times \left(1 - \frac{V_O}{V_{IN}} - (t_1 + t_2) \times f_{SW} \right) \times \left(I_{LOAD}^2 + \frac{\Delta I^2}{12} \right) \quad (32)$$

$$P_{DIODE} = V_f \times I_{LOAD} \times (t_1 + t_2) \times f_{SW} \quad (33)$$

$$P_{QSR(GATE)} = Q_{g(TOTAL)} \times V_g \times f_{SW} \quad (34)$$

where

- P_{DIODE} = body diode losses
- t_1 = body diode conduction prior to turn on of channel = 10 ns for predictive gate drive
- t_2 = body diode conduction after turn off of channel = 10 ns for predictive gate drive
- V_f = body diode forward voltage

Estimating the body diode losses based on a forward voltage of 1.2 V gives 0.142 W. The gate losses are unknown at this time so assume 0.1 W gate losses. This leaves 0.258 W for conduction losses. Using this figure a target $R_{DS(on)}$ of 1.1 mΩ was calculated. This is an extremely low value. It is not possible to meet this without paralleling multiple MOSFETs. Paralleling MOSFETs increases the gate capacitance and slows down switching speeds. This increases body diode and gate losses.

The PH2625L from Philips was chosen. Using the parameters from its data sheet the actual expected power losses were calculated. Conduction loss is 0.527 W, body diode loss is 0.142 W and the gate loss was 0.174 W. This totals 0.843 W associated with the rectifier MOSFET. This is somewhat greater than the initial allowance. Because of this the converter may not hit its efficiency figure at the maximum load.

Two other criteria should be verified before finalizing on the rectifier MOSFET. One is the requirement to ensure that predictive gate drive functions correctly. The maximum turn off delay of the PH2625L is 67 ns. The minimum turn on delay of the PH6325L is 25 ns. These devices easily meet the 100 ns difference requirement.

Secondly the ratio between C_{gs} and C_{gd} should be greater than 1. The C_{gs} of the PH2625L is 2133 pF and the C_{gd} is 1622 pF, so the $C_{gs}:C_{gd}$ ratio is 1.3:1. This helps reduce the risk of dv/dt induced turn on of the rectifier MOSFET. If this is likely to be a problem a small resistor may be added in series with the boost capacitor, C_{BOOST} .

3.2 Component Selection for TPS40074

3.2.1 Timing Resistor, R_T

The timing resistor is calculated using the following equation.

$$R_T = \frac{1}{f_{SW} \times 17.82 \times 10^{-6}} - 23 \quad (35)$$

This gives a resistor value of 117.3 kΩ. Using the E24 range of resistor values a 118-kΩ resistor was selected. The nominal frequency using this resistor is 398 kHz.

3.2.2 Feed Forward and UVLO Resistor, R_{KFF}

A resistor connected to the KFF pin of the device feeds into the ramp generator. This resistor provides current into the ramp generator proportional to the input voltage. The ramp is then adjusted to compensate for different input voltages. It provides the voltage feed forward feature of the TPS40074.

The same resistor also sets the under voltage lock out point. The input start voltage should be used to calculate a value for R_{KFF} . For this converter the minimum input voltage is 10.8 V however due to tolerances in the device, a start voltage of 15% less than the minimum input voltage is selected. The start voltage for R_{KFF} calculation is 9.18 V. Using [Equation 36](#) R_{KFF} can be selected.

$$R_{KFF} = 0.131 \times R_T \times V_{UVLO(on)} - 1.61 \times 10^{-3} \times V_{UVLO(on)}^2 + 1.886 \times V_{UVLO} - 1.363 - 0.02 \times R_T - 4.87 \times 10^{-5} \times R_T^2 \quad (36)$$

where

TPS40074

SLUS617B-APRIL 2005-REVISED OCTOBER 2006

- $V_{UVLO(on)}$ is in volts
- R_{KFF} and R_T are in kΩ

This equation gives a R_{KFF} value of 154.7 kΩ. The closest lower standard value should be selected. For this design and using E24 resistor range 154 kΩ was chosen. This yields a typical start voltage of 9.14 V.

3.2.3 Soft Start Capacitor

It is good practice to limit the rise time of the output voltage. This helps prevent output overshoot and possible damage to the load. The selection of the soft start time is arbitrary, but it must meet one condition; it should be greater than the time constant of the output filter, L and C_O . This time is given by [Equation 37](#)

$$t_{START} \geq 2\pi \times \sqrt{L \times C_O} \quad (37)$$

The soft-start time must be greater than 0.281 ms. A time of 1 ms was chosen, this time also helps keep the initial input current during start up low. The value of C_{SS} can be calculated using [Equation 38](#).

$$C_{SS} \geq \frac{12 \times 10^{-6}}{0.7} \times t_{START} \quad (38)$$

C_{SS} should be greater than 17 nF, a 22 nF MLCC was chosen. The calculated start time using this capacitor is 1.28 ms.

3.2.4 Short Circuit Protection, R_{ILIM} and C_{ILIM}

Short circuit protection is programmed using the R_{ILIM} resistor. Selection of this resistor depends on the $R_{DS(on)}$ of the switching MOSFET selected and the required short circuit current trip point, I_{SCP} . The minimum I_{SCP} is limited by the inductor peak current, the output voltage, the output capacitor and the soft start time. Their relationship is given by [Equation 39](#). A short circuit current trip point greater than that calculated by this equation should be used.

$$I_{SCP} \geq \frac{C_O \times V_{OUT}}{t_{START}} + I_{LOAD} + \frac{\Delta I}{2} \quad (39)$$

The minimum short circuit current trip point for this design is 16.65 A. This value is used in [Equation 40](#) to calculate the minimum R_{ILIM} value.

$$R_{ILIM} = \frac{100 \times (R_{DS(on)MAX} \times I_{SCP} + V_{ILIM(min)}) + 4.5 V}{109 \times I_{LIM(max)}} \quad (40)$$

R_{ILIM} is calculated to be 1.59 kΩ. The closest standard value greater than 1.59 kΩ is chose, this is 1.62 kΩ. To verify that the short circuit current requirements are met the minimum and maximum short circuit current can be calculated using [Equation 41](#) and [Equation 42](#).

$$I_{SCP(min)} = \frac{1.09 \times I_{ILIM(min)} \times R_{ILIM} - 0.045 V - V_{ILIM(max)}}{R_{DS(on)MAX}} \quad (41)$$

$$I_{SCP(max)} = \frac{1.09 \times I_{ILIM(max)} \times R_{ILIM} - 0.045 V - V_{ILIM(min)}}{R_{DS(on)MIN}} \quad (42)$$

The minimum I_{SCP} is 17.05 A and the maximum is 47.04 A.

It is recommended to add a small capacitor, C_{ILIM} , across R_{ILIM} . The value of this capacitor should be less than that calculated in [Equation 43](#).

$$C_{ILIM(max)} = \frac{V_O \times 0.2}{V_{IN} \times R_{ILIM} \times f_{SW}} \quad (43)$$

This equation yields a maximum C_{ILIM} of 38 pF. A value half this is chosen, 22 pF.

3.2.5 Voltage Decoupling Capacitors, C_{DBP} , C_{LVB_P} and C_{VDD}

Several pins on the TPS40074 have DC voltages. It is recommended to add small decoupling capacitors to these pins. Below is a list of the recommended values.

- $C_{DBP} = 1.0 \mu F$
- $C_{LVBP} = 0.1 \mu F$
- $C_{VDD} = 4.7 \mu F$

3.2.6 Boost Voltage, C_{BOOST} and D_{BOOST} (optional)

A capacitor charge pump or boost circuit is required to drive an N-channel MOSFET in the switch location of a buck converter. The TPS40074 contains the elements for this boost circuit. The designer just has to add a capacitor, C_{BOOST} , from the switch node of the buck power stage to the BOOST pin of the device. Selection of this capacitor is based on the total gate charge of the switching MOSFET and the allowable ripple on the boost voltage, ΔV_{BOOST} . A ripple of 0.15 V is assumed for this design. Using these two parameters and [Equation 44](#) the minimum value for C_{BOOST} can be calculated.

$$C_{BOOST} > \frac{Q_{g(TOTAL)}}{\Delta V_{BOOST}} \quad (44)$$

The total gate charge of the switching MOSFET is 13.3 nC. A minimum C_{BOOST} of 0.089 μF is required. A 0.1 μF capacitor was chosen.

This capacitor must be able to withstand the maximum voltage on DBP (10 V in this instance). A 50 V capacitor is used for expediency.

To reduce losses in the TPS40074 and to increase the available gate voltage for the switching MOSFET an external diode can be added between the DBP pin and the BOOST pin of the device. A small signal schottky should be used here, such as the BAT54.

3.3 Closing the Feedback Loop, R_{Z1} , R_{P1} , R_{PZ2} , R_{SET1} , R_{SET2} , C_{Z2} , C_{P2} and C_{PZ1}

A graphical method is used to select the compensation components. This is a standard feedforward buck converter. Its PWM gain is shown in [Equation 45](#).

$$K_{PWM} \approx \frac{V_{UVLO}}{1V} \quad (45)$$

The gain of the output L-C filter is given by [Equation 46](#)

$$K_{LC} = \frac{(1 + s \times ESR \times C_O)}{1 + s \times \left(\frac{L}{R_{LOAD}} \right) + s^2 \times L \times C_O} \quad (46)$$

The PWM and LC gain is, shown in [Equation 47](#).

$$G_e(s) = K_{PWM} \times K_{LC} = \frac{V_{UVLO}}{1V} \times \frac{(1 + s \times ESR \times C_O)}{1 + s \times \left(\frac{L}{R_{LOAD}} \right) + s^2 \times L \times C_O} \quad (47)$$

To describe this in a Bode plot, the DC gain must be expressed in dB. The DC gain is equal to K_{PWM} . To express this in dB we take its LOG and multiple by 20. For this converter the DC gain is shown in [Equation 48](#).

$$DCGAIN = 20 \times \text{LOG} \left(\frac{V_{UVLO}}{1V} \right) = 20 \times \text{LOG}(9.14) = 19.3 \text{ dB} \quad (48)$$

The pole and zero frequencies should be calculated, also. A double pole is associated with the L-C and a zero is associated with the ESR of the output capacitor. The frequency at where these occur can be calculated using the following two equations.

TPS40074

SLUS617B-APRIL 2005-REVISED OCTOBER 2006

$$f_{LC_Pole} = \frac{1}{2\pi \times \sqrt{L \times C_O}} = 3559 \text{ Hz} \quad (49)$$

$$f_{ESR_Zero} = \frac{1}{2\pi \times ESR \times C_O} = 8377 \text{ Hz} \quad (50)$$

The resulting bode plot is shown in [Figure 15](#).

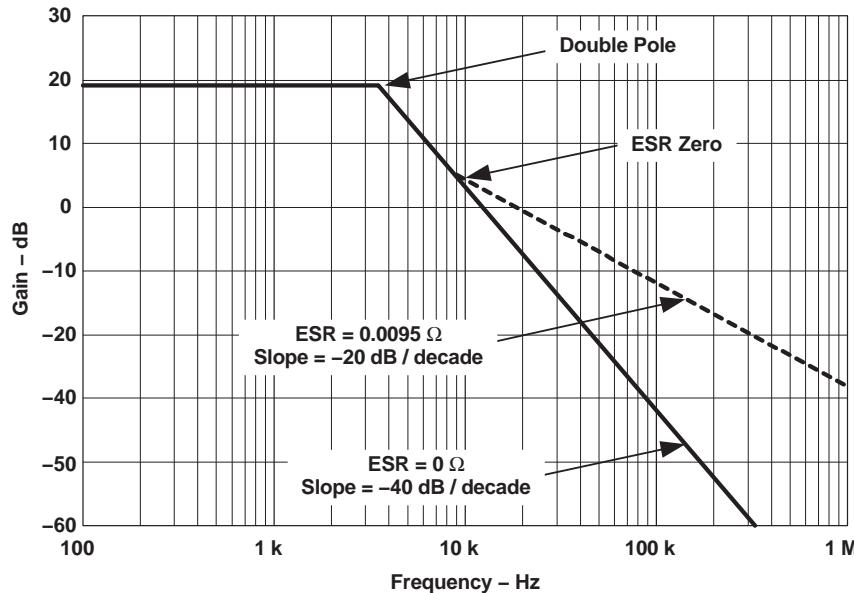

Figure 15. PWM and LC Filter Gain

The next step is to establish the required compensation gain to achieve the desired overall system response. The target response is to have the crossover frequency between 1/10 to 1/4 times the switching frequency. To have a phase margin greater than 45° and a gain margin greater than 6 dB.

A Type III compensation network, as shown in [Figure 16](#), was used for this design. This network gives the best overall flexibility for compensating the converter.

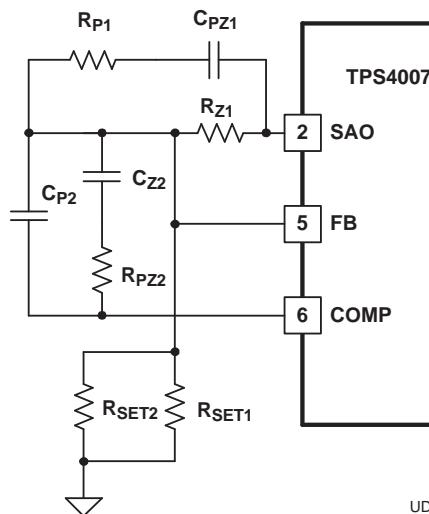

Figure 16. Type III Compensation with TPS40074

A typical bode plot to this type of compensation network is shown in [Figure 17](#).

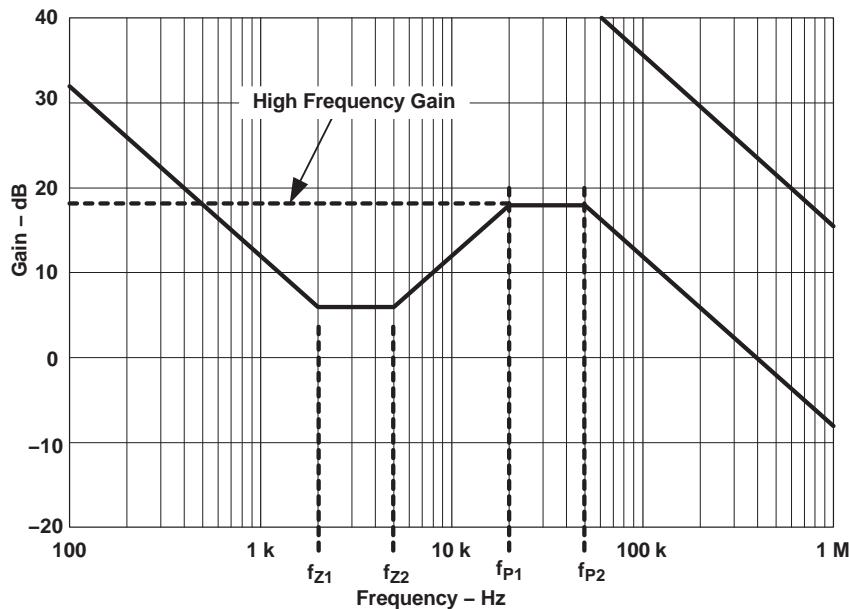

Figure 17. Type III Compensation Bode Plot

The high frequency gain and the break (pole and zero) frequencies are calculated using the following equations.

$$V_O = V_{FB} \times \frac{R_{Z1} + R_{SET}}{R_{SET}} \quad (51)$$

$$R_{SET} = \frac{R_{SET1} \times R_{SET2}}{R_{SET1} + R_{SET2}} \quad (52)$$

$$GAIN = \frac{R_{PZ2}}{\left(\frac{R_{Z1} \times R_{P1}}{R_{Z1} + R_{P1}} \right)} \quad (53)$$

$$f_{P1} = \frac{1}{2\pi \times R_{P1} \times C_{PZ1}} \quad (54)$$

$$f_{P2} = \frac{C_{P2} + C_{Z2}}{2\pi \times R_{PZ2} \times C_{P2} \times C_{Z2}} \cong \frac{1}{2\pi \times R_{PZ2} \times C_{P2}} \quad (55)$$

$$f_{Z1} = \frac{1}{2\pi \times R_{Z1} \times C_{PZ1}} \quad (56)$$

$$f_{Z2} = \frac{1}{2\pi \times (R_{PZ2} + R_{P1}) \times C_{Z2}} \cong \frac{1}{2\pi \times R_{PZ2} \times C_{Z2}} \quad (57)$$

Using this PWM and L-C bode plot the following actions ensure stability.

1. Place two zero's close to the double pole, i.e. $f_{Z1} = f_{Z2} = 3559$ Hz
2. Place a pole at one octave below the desired crossover frequency. The crossover frequency was selected as one quarter the switching frequency, $f_{CO} = 100$ kHz, $f_{P1} = 50$ kHz
3. Place the second pole about an octave above f_{CO} . This ensures that the overall system gain falls off quickly to give good gain margin, $f_{P2} = 200$ kHz
4. The high-frequency gain is sufficient to ensure 0 dB at the required crossover frequency, $GAIN = -1 \times GAIN$ of PWM and LC at the crossover frequency, $GAIN = 17.2$ dB, or 7.24

Desired frequency response and resultant overall system response can be seen in [Figure 18](#).

TPS40074

SLUS617B-APRIL 2005-REVISED OCTOBER 2006

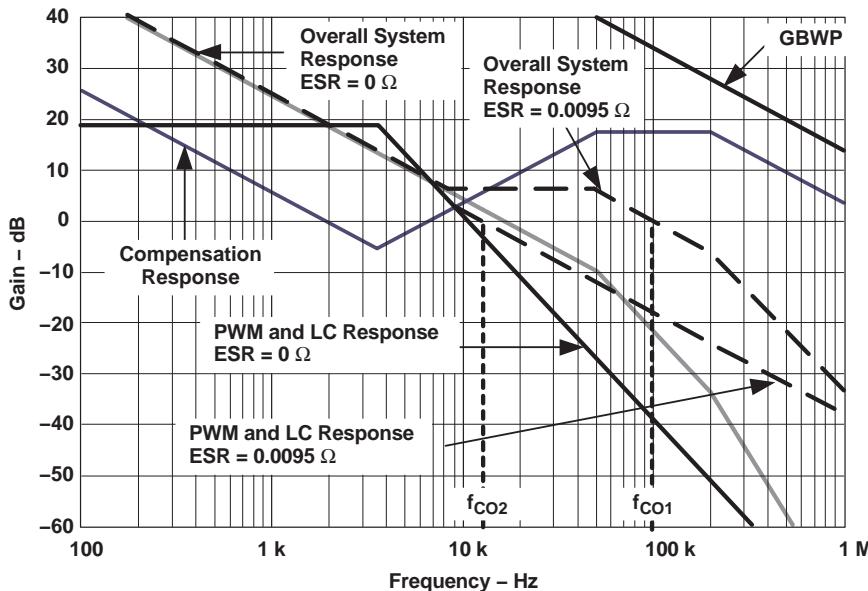

Figure 18. Overall System Bode Plot

Using these values and the equations above the resistors and capacitors around the compensation network can be calculated.

1. Set $R_{Z1} = 10 \text{ k}\Omega$.
2. Calculate R_{SET} using [Equation 51](#); $R_{SET} = 8750 \Omega$. Two resistors in parallel, R_{SET1} and R_{SET2} , are used to make up R_{SET} . $R_{SET1} = 9.53 \text{ k}\Omega$, $R_{SET2} = 105 \text{ k}\Omega$.
3. Using [Equation 56](#) and $f_{Z1} = 3559 \text{ Hz}$, C_{PZ1} can be calculated to be 4.47 nF ; $C_{PZ1} = 4.7 \text{ nF}$.
4. F_{P1} and [Equation 54](#) yields R_{P1} to be 677Ω , $R_{P1} = 680 \Omega$.
5. The required gain of 17.2 dB (7.24) and [Equation 54](#) sets the value for R_{PZ1} . Note actual gain used for this calculation was 20 dB (10), this ensures that the gain of the transfer function is high enough, $R_{PZ1} = 6.2 \text{ k}\Omega$.
6. C_{Z2} is calculated using [Equation 57](#) and the desired frequency for the second zero, $C_{Z2} = 6.8 \text{ nF}$.
7. C_{P2} is calculated using the second pole frequency and [Equation 55](#), $C_{P2} = 150 \text{ pF}$.

Using MathCAD the above values were used to draw the actual Bode plot for gain and phase. From these plots the crossover frequency, phase margin and gain margin can be recorded.

Table 3. Theoretical System Stability Results

ESR (Ω)	CROSSOVER FREQUENCY (kHz)	PHASE MARGIN (°)	GAIN MARGIN (dB)
0	23.1	72	> 46
0.0095	98.6	78.8	> 33

(1) The marketing status values are defined as follows:

ACTIVE: Product device recommended for new designs.

LIFEBUY: TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.

NRND: Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.

PREVIEW: Device has been announced but is not in production. Samples may or may not be available.

OBsolete: TI has discontinued the production of the device.

(2) Eco Plan - The planned eco-friendly classification: Pb-Free (RoHS), Pb-Free (RoHS Exempt), or Green (RoHS & no Sb/Br) - please check <http://www.ti.com/productcontent> for the latest availability information and additional product content details.

TBD: The Pb-Free/Green conversion plan has not been defined.

Pb-Free (RoHS): TI's terms "Lead-Free" or "Pb-Free" mean semiconductor products that are compatible with the current RoHS requirements for all 6 substances, including the requirement that lead not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, TI Pb-Free products are suitable for use in specified lead-free processes.

Pb-Free (RoHS Exempt): This component has a RoHS exemption for either 1) lead-based flip-chip solder bumps used between the die and package, or 2) lead-based die adhesive used between the die and leadframe. The component is otherwise considered Pb-Free (RoHS compatible) as defined above.

Green (RoHS & no Sb/Br): TI defines "Green" to mean Pb-Free (RoHS compatible), and free of Bromine (Br) and Antimony (Sb) based flame retardants (Br or Sb do not exceed 0.1% by weight in homogeneous material)

(3) MSL, Peak Temp. - The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

(4) There may be additional marking, which relates to the logo, the lot trace code information, or the environmental category on the device.

(5) Multiple Device Markings will be inside parentheses. Only one Device Marking contained in parentheses and separated by a "-" will appear on a device. If a line is indented then it is a continuation of the previous line and the two combined represent the entire Device Marking for that device.

(6) Lead/Ball Finish - Orderable Devices may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead/Ball Finish values may wrap to two lines if the finish value exceeds the maximum column width.

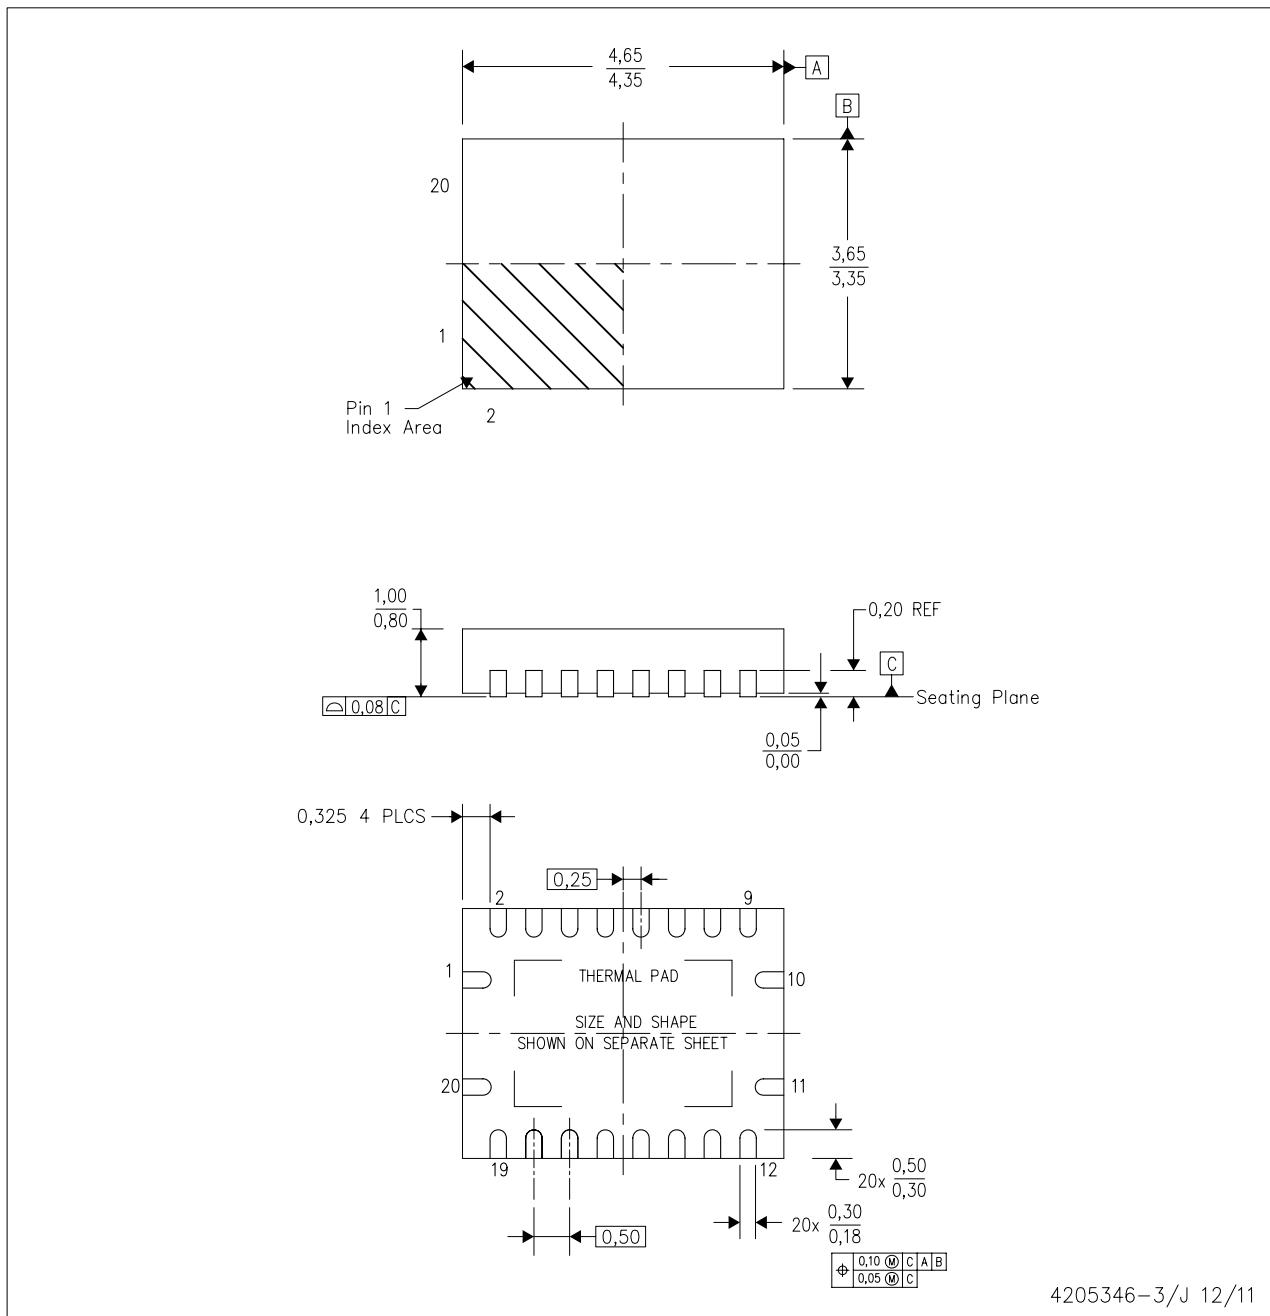

Important Information and Disclaimer: The information provided on this page represents TI's knowledge and belief as of the date that it is provided. TI bases its knowledge and belief on information provided by third parties, and makes no representation or warranty as to the accuracy of such information. Efforts are underway to better integrate information from third parties. TI has taken and continues to take reasonable steps to provide representative and accurate information but may not have conducted destructive testing or chemical analysis on incoming materials and chemicals. TI and TI suppliers consider certain information to be proprietary, and thus CAS numbers and other limited information may not be available for release.

In no event shall TI's liability arising out of such information exceed the total purchase price of the TI part(s) at issue in this document sold by TI to Customer on an annual basis.

IMPORTANT NOTICE

Texas Instruments Incorporated and its subsidiaries (TI) reserve the right to make corrections, enhancements, improvements and other changes to its semiconductor products and services per JESD46, latest issue, and to discontinue any product or service per JESD48, latest issue. Buyers should obtain the latest relevant information before placing orders and should verify that such information is current and complete. All semiconductor products (also referred to herein as "components") are sold subject to TI's terms and conditions of sale supplied at the time of order acknowledgment.

TI warrants performance of its components to the specifications applicable at the time of sale, in accordance with the warranty in TI's terms and conditions of sale of semiconductor products. Testing and other quality control techniques are used to the extent TI deems necessary to support this warranty. Except where mandated by applicable law, testing of all parameters of each component is not necessarily performed.

TI assumes no liability for applications assistance or the design of Buyers' products. Buyers are responsible for their products and applications using TI components. To minimize the risks associated with Buyers' products and applications, Buyers should provide adequate design and operating safeguards.

TI does not warrant or represent that any license, either express or implied, is granted under any patent right, copyright, mask work right, or other intellectual property right relating to any combination, machine, or process in which TI components or services are used. Information published by TI regarding third-party products or services does not constitute a license to use such products or services or a warranty or endorsement thereof. Use of such information may require a license from a third party under the patents or other intellectual property of the third party, or a license from TI under the patents or other intellectual property of TI.

Reproduction of significant portions of TI information in TI data books or data sheets is permissible only if reproduction is without alteration and is accompanied by all associated warranties, conditions, limitations, and notices. TI is not responsible or liable for such altered documentation. Information of third parties may be subject to additional restrictions.

Resale of TI components or services with statements different from or beyond the parameters stated by TI for that component or service voids all express and any implied warranties for the associated TI component or service and is an unfair and deceptive business practice. TI is not responsible or liable for any such statements.

Buyer acknowledges and agrees that it is solely responsible for compliance with all legal, regulatory and safety-related requirements concerning its products, and any use of TI components in its applications, notwithstanding any applications-related information or support that may be provided by TI. Buyer represents and agrees that it has all the necessary expertise to create and implement safeguards which anticipate dangerous consequences of failures, monitor failures and their consequences, lessen the likelihood of failures that might cause harm and take appropriate remedial actions. Buyer will fully indemnify TI and its representatives against any damages arising out of the use of any TI components in safety-critical applications.

In some cases, TI components may be promoted specifically to facilitate safety-related applications. With such components, TI's goal is to help enable customers to design and create their own end-product solutions that meet applicable functional safety standards and requirements. Nonetheless, such components are subject to these terms.

No TI components are authorized for use in FDA Class III (or similar life-critical medical equipment) unless authorized officers of the parties have executed a special agreement specifically governing such use.

Only those TI components which TI has specifically designated as military grade or "enhanced plastic" are designed and intended for use in military/aerospace applications or environments. Buyer acknowledges and agrees that any military or aerospace use of TI components which have **not** been so designated is solely at the Buyer's risk, and that Buyer is solely responsible for compliance with all legal and regulatory requirements in connection with such use.

TI has specifically designated certain components as meeting ISO/TS16949 requirements, mainly for automotive use. In any case of use of non-designated products, TI will not be responsible for any failure to meet ISO/TS16949.
